Lab Code	Lab Name	Credit
ITC801	Blockchain and DLT Lab	1

Programme Outcomes: The graduate will be able to:

PO1	Engineering Knowledge: Apply knowledge of mathematics, natural science, computing, engineering fundamentals and an engineering specialization as specified in WK1 to WK4 respectively to develop to the solution of complex engineering problems.
PO2	Problem Analysis: Identify, formulate, review research literature and analyze complex engineering problems reaching substantiated conclusions with consideration for sustainable development. (WK1 to WK4)
PO3	Design/Development of Solutions: Design creative solutions for complex engineering problems and design / develop systems /components / processes to meet identified needs with consideration for the public health and safety, whole-life cost, net zero carbon, culture, society and environment as required. (WK5)
PO4	PO4: Conduct Investigations of Complex Problems: Conduct investigations of complex engineering problems using research-based knowledge including design of experiments, modelling, analysis & interpretation of data to provide valid conclusions. (WK8).
PO5	Engineering Tool Usage: Create, select and apply appropriate techniques, resources and modern engineering & IT tools, including prediction and modelling recognizing their limitations to solve complex engineering problems. (WK2 and WK6)
PO6	The Engineer and The World: Analyze and evaluate societal and environmental aspects while solving complex engineering problems for its impact on sustainability with reference to economy, health, safety, legal framework, culture and environment. (WK1, WK5, and WK7).
PO7	Ethics: Apply ethical principles and commit to professional ethics, human values, diversity and inclusion; adhere to national & international laws. (WK9)
PO8	Individual and Collaborative Team work: Function effectively as an individual, and as a member or leader in diverse/multi-disciplinary teams.
PO9	Communication: Communicate effectively and inclusively within the engineering community and society at large, such as being able to comprehend and write effective reports and design documentation, make effective presentations considering cultural, language, and learning differences

**VIVEKANAND EDUCATION SOCIETY'S
INSTITUTE OF TECHNOLOGY**
Department of Information Technology
Academic Year: 2025-26

PO10	Project Management and Finance: Apply knowledge and understanding of engineering management principles and economic decision-making and apply these to one's own work, as a member and leader in a team, and to manage projects and in multidisciplinary environments.
PO11	Life-Long Learning: Recognize the need for, and have the preparation and ability for i) independent and life-long learning ii) adaptability to new and emerging technologies and iii) critical thinking in the broadest context of technological change.
PSO 1	Computing & Emerging Technology: Apply core computing and modern technologies, such as AI, Cloud Computing, IoT, cybersecurity, and data-driven tools, to build efficient and innovative solutions.
PSO 2	Professionalism & Innovation : Demonstrate ethics, teamwork, and an entrepreneurial mindset to deliver sustainable solutions for society.

Course Outcomes: Student will be able	
ITC801.1	Describe the basic concept of Blockchain and Distributed Ledger Technology.
ITC801.2	Interpret the knowledge of the Bitcoin network, nodes, keys, wallets and transactions
ITC801.3	Implement smart contracts in Ethereum using different development frameworks.
ITC801.4	Develop applications in permissioned Hyperledger Fabric network.
ITC801.5	Interpret different Crypto assets and Crypto currencies
ITC801.6	The use of Blockchain with AI, IoT and Cyber Security using case studies.

ITC801 : Blockchain & DLT Lab

Experiment No. 01

Aim: Write a Python program to understand SHA and Cryptography in Blockchain, Merkle root tree hash

Roll No.	38
Name	Aryan Patankar
Class	D20A
Subject	ITC801: Blockchain and DLT Lab
CO Mapped	CO1: Describe the basic concept of Blockchain and Distributed Ledger Technology. CO2: Interpret the knowledge of the Bitcoin network, nodes, keys, wallets and transactions CO5: Interpret different Crypto assets and Crypto currencies

EXPERIMENT NO.1

Name:Aryan Anil Patankar

Class:D20A

Roll No:38

Batch:B

Aim: Write a Python program to understand SHA and Cryptography in Blockchain, Merkle root tree hash.

1. Cryptographic Hash Functions in Blockchain

Cryptographic hash functions are mathematical algorithms that take an input of any length and produce a fixed-length output string known as a hash value. In blockchain technology, they play a crucial role in ensuring data integrity, security, and immutability. These functions must be cryptographically secure, meaning they exhibit specific properties that make them resistant to attacks.

Properties of Cryptographic Hash Functions

- **Collision Resistant:** It is computationally infeasible to find two different inputs (m_1 and m_2) that produce the same hash output.
- **Preimage Resistant:** Given a hash value h , it is difficult to find the original input m that produced h .
- **Second Preimage Resistant:** Given an input m_1 , it is hard to find another input m_2 that produces the same hash as m_1 .
- **Large Output Space:** Brute-force attacks require checking an enormous number of possibilities.
- **Deterministic:** The same input always produces the same output.
- **Avalanche Effect:** A small change in the input causes a significant change in the output.

- **Puzzle Friendliness:** Even if part of the output is known, predicting the rest is impossible.
- **Fixed-Length Mapping:** Outputs are always of a consistent length regardless of input size.

How Hash Functions Work in Blockchain

Hash functions convert variable-length data (e.g., transactions) into fixed-size outputs. In blockchain, this process involves encryption (generating the hash) and potential decryption for verification. Common algorithms include SHA-256, which always outputs 256 bits (32 bytes).

Properties of SHA-256

SHA-256 (Secure Hash Algorithm – 256-bit) belongs to the SHA-2 family and is one of the most commonly used hashing algorithms in blockchain technology. It converts any input data into a secure 256-bit hash value, regardless of the input's original size.

- **Fixed 256-bit Output:** SHA-256 always produces a hash of exactly 256 bits, usually shown as 64 hexadecimal characters, no matter how large the input is.
- **High Security Strength:** It is widely trusted for modern cryptography and is a standard choice in blockchain networks for strong protection.
- **Collision Resistance:** The chance that two different pieces of data generate the same hash is extremely rare, ensuring reliable data integrity.
- **Avalanche Property:** Even the smallest change in input data results in a completely different hash output, making unauthorized modifications easy to detect.
- **Irreversible (One-Way Function):** It is practically impossible to reverse the hash and recover the original input data.

2. What is a Merkle Tree?

A Merkle Tree, also known as a hash tree, is a binary tree data structure used for efficient data verification and synchronization. Each leaf node represents the hash of a data block (e.g., a transaction), while each non-leaf node is the hash of its child nodes. The tree culminates in a single root hash (Merkle root), which serves as a digital fingerprint of the entire dataset.

In blockchain, Merkle Trees organize transactions per block, replacing less efficient structures like linked lists. They leverage cryptographic hashes and hash pointers (pointers that include both data location and its hash for verification).

Structure of a Merkle Tree

A Merkle Tree follows a layered hierarchical arrangement. It begins with individual transaction hashes at the bottom level. These hashes are merged pairwise to form parent nodes, continuing upward through multiple levels until reaching the topmost hash, the **Merkle Root**, which summarizes and secures all transactions within the block.

1. **Leaf Nodes:** These are the hashes of individual transactions

in a block. Each transaction is first hashed to form a leaf node.

2. Intermediate (Parent) Nodes: Pairs of leaf nodes are combined and hashed again to form parent nodes. This process continues upward, combining child nodes at each level.

3. Root Node (Merkle Root): The topmost node of the tree, representing all transactions in the block. If any transaction changes, the Merkle Root changes, making tampering detectable.

2. Merkle Root

The Merkle Root is the **topmost hash** of the Merkle Tree. It acts as a summary of all transactions in a block.

If any transaction is changed, its hash changes, which affects the Merkle Root. Since the Merkle Root is stored in the block header, this makes tampering easy to detect.

3. What is a Cryptographic Puzzle and Explanation of the Golden Nonce

A cryptographic puzzle in blockchain refers to a complex mathematical problem that miners must solve to validate transactions and add new blocks. It is central to the Proof of Work (PoW) consensus mechanism, particularly in networks like Bitcoin. The puzzle involves finding a specific hash value that meets the network's difficulty criteria, such as being below a certain target threshold. This requires intensive computations, making it resource-heavy to solve but easy to verify.

Key Aspects of Cryptographic Puzzles

- **Purpose:** Secures the network by preventing easy tampering, double-spending, or counterfeiting. It ensures consensus without trusting any single party.

- **Process:** Miners hash block data (including transactions and a nonce) repeatedly until the output satisfies conditions. The difficulty adjusts dynamically (e.g., every 2016 blocks in Bitcoin) to maintain a ~10-minute block time.
- **Computational Intensity:** Involves brute-force trials; with millions of miners, it takes significant power and time.
- **Security:** Limits total coin supply (e.g., 21 million Bitcoins) and makes illicit changes expensive.

The "Golden Nonce" refers to the specific nonce value that, when combined with the block data and hashed, produces a valid hash solving the puzzle. It is the "winning" nonce that allows a miner to claim the block reward (e.g., 6.25 Bitcoins). Miners iterate through nonce values (a 32-bit number) until this golden nonce is found, after which the block is broadcast for verification

4. Working of Merkle Tree

The Merkle Tree works by organizing and summarizing all transactions in a block into a single hash (the Merkle Root) so that data can be verified efficiently and securely.

The process follows these steps:

- **Hashing Transactions:** Each transaction in the block is first hashed using a cryptographic hash function, usually SHA-256. These hashes form the leaf nodes of the Merkle Tree.

Example:

Transactions: T1, T2,
T3, T4 Hashes: H(T1),
H(T2), H(T3), H(T4)

- **Pairing and Hashing:** The leaf nodes are grouped in pairs. Each pair of hashes is concatenated (joined together) and then hashed again to create a parent node. If the number of transactions is odd, the last hash is duplicated to form a pair. This ensures that every level of the tree has an even number of nodes.

Example:

- Pair 1: $H(T1) + H(T2) \rightarrow \text{Hash} = H12$
- Pair 2: $H(T3) + H(T4) \rightarrow \text{Hash} = H34$

- **Building the Tree:** The pairing and hashing process continues up the tree, combining parent nodes to create new higher-level nodes.

Example:

$$H12 + H34 \rightarrow \text{Hash} = H123$$

- **Creating the Merkle Root:** This process repeats until only one hash remains at the top of the tree. This top-level hash is called the Merkle Root, which represents all transactions in the block.

- **Verification:** To verify that a transaction exists in a block, a Merkle Proof is used. Instead of checking every transaction, only a small number of hashes along the path from the transaction leaf to the Merkle Root are needed. This makes verification fast and efficient, even for large blocks of data.

- **Example:**

To verify T1: Use H(T2) and H34 along with H(T1) to recalculate H1234. If it matches the Merkle Root, T1 is valid.

- **Tamper Detection:** If any transaction is modified, its hash changes. This change propagates up the tree and alters the

Merkle Root. Since the Merkle Root is stored in the block header, any tampering becomes immediately obvious.

Example:

If T3 changes → H(T3) changes → H34 changes → H1234 changes → Merkle Root mismatch.

5. Benefits of Merkle Tree

- **Efficient Verification:** Only a small number of hashes are needed to verify a transaction using a Merkle Proof, so checking data is fast even for large blocks.
- **Data Integrity:** Any change in a transaction alters the Merkle Root, making it easy to detect tampering.
- **Reduced Storage:** Instead of storing all transaction data in the block header, only the Merkle Root is stored, saving space.
- **Scalability:** Merkle Trees allow blockchains to handle a large number of transactions without slowing down verification.
- **Security:** The structure ensures that transactions cannot be altered without being noticed, keeping the blockchain secure.

6. Use Cases of Merkle Tree

Merkle Trees are versatile, with primary applications in blockchain and beyond:

- **Blockchain Transactions:** Organize and verify transactions in blocks; Merkle root in headers ensures integrity.
- **Proof of Membership:** Miners or users prove a transaction's inclusion using a Merkle proof (path of hashes), requiring only $O(\log n)$ data.
- **Simple Payment Verification (SPV):** Lightweight clients verify transactions without the full blockchain.

- **Coinbase Transactions:** Included in every block's tree for new coin creation.
- **Distributed Systems:** Ensure data consistency across nodes; detect inconsistencies in replicas (e.g., Apache Cassandra databases).
- **File Systems:** Verify content in systems like IPFS or BitTorrent.
- **Inconsistency Detection:** Compare root hashes to pinpoint data differences quickly.

In Bitcoin and other blockchains, they enable trustless, efficient operations in peer-to-peer networks.

Colab Notebook:
[Blockchain Exp1](#)

Code & Output:

1. Hash Generation using SHA-256: Developed a Python program to compute a SHA-256 hash for any given input string using the hashlib library.

```
import hashlib

def create_hash(string):
    # Create a hash object using SHA-256 algorithm
    hash_object = hashlib.sha256()

    # Convert the string to bytes and update the hash object
    hash_object.update(string.encode('utf-8'))

    # Get the hexadecimal representation of the hash
    hash_string = hash_object.hexdigest()

    # Return the hash string
    return hash_string

# Example usage
input_string = input("Enter a string: ")
hash_result = create_hash(input_string)
print("Hash:", hash_result)
```

... Enter a string: aryanpatankar
Hash: a224b5173a85e4214fbf6d88600d3b4dca7b9523032095bbdb0584ed4e73fa87

2.Target Hash Generation with Nonce: Created a program to generate a hash code by concatenating a user input string and a nonce value to simulate the mining process.

▶ **# Program 2: Generating Target Hash with Input String and Nonce**
`import hashlib`

Get user input
`input_string = input("Enter a string: ")`
`nonce = input("Enter the nonce: ")`

Concatenate the string and nonce
`hash_string = input_string + nonce`

Calculate the hash using SHA-256
`hash_object = hashlib.sha256(hash_string.encode('utf-8'))`
`hash_code = hash_object.hexdigest()`

Print the hash code
`print("Hash Code:", hash_code)`

*** Enter a string: Aryan
Enter the nonce: 1
Hash Code: 52d2de03394c757ee98f7cd8b73a72c99bfa8d953cbfde1905f948b6fc51c61d

3.Proof-of-Work Puzzle Solving: Implemented a program to find the nonce that, when combined with a given input string, produces a hash starting with a specified number of leading zeros.

```
🕒 # Program 3: Solving Cryptographic Puzzle for Leading Zeros
import hashlib

def find_nonce(input_string, num_zeros):
    nonce = 0
    hash_prefix = '0' * num_zeros

    while True:
        # Concatenate the string and nonce
        hash_string = input_string + str(nonce)

        # Calculate the hash using SHA-256
        hash_object = hashlib.sha256(hash_string.encode('utf-8'))
        hash_code = hash_object.hexdigest()

        # Check if the hash code has the required number of leading zeros
        if hash_code.startswith(hash_prefix):
            print("Hash:", hash_code)
            return nonce

        nonce += 1

# Get user input
input_string = "Aryan"
num_zeros = 1

# Find the expected nonce
expected_nonce = find_nonce(input_string, num_zeros)

# Print the expected nonce
print("Input String:", input_string)
print("Leading Zeros:", num_zeros)
print("Expected Nonce:", expected_nonce)
```

```
*** Hash: 043a2485b4ad07329119b33b48423d5477bf17a2afab3fe342b67cd0a727dde5
    Input String: Aryan
    Leading Zeros: 1
    Expected Nonce: 20
```

4.Merkle Tree Construction: Built a Merkle Tree from a list of transactions by recursively hashing pairs of transaction hashes, doubling up last nodes if needed, and generated the Merkle Root hash for blockchain transaction integrity.

```
import hashlib
```

```
def build_merkle_tree(transactions):
```

```
    if len(transactions) == 0:
```

```
        return None
```

```
    # Hash each transaction initially
```

```
    hashed_transactions = [
```

```
        hashlib.sha256(t.encode('utf-8')).hexdigest()
```

```
        for t in transactions
```

```
    ]
```

```
    print("Initial Hashed Transactions:", hashed_transactions)
```

```
    # If only one transaction, it is the Merkle Root
```

```
    if len(hashed_transactions) == 1:
```

```
        return hashed_transactions[0]
```

```
    # Iterative construction of the Merkle Tree
```

```
    current_level = hashed_transactions
```

```
    level = 1
```

```

while len(current_level) > 1:
    print(f"\nLevel {level} Hashes:")

    # If odd number of hashes, duplicate the last one
    if len(current_level) % 2 != 0:
        current_level.append(current_level[-1])

    new_level = []

    for i in range(0, len(current_level), 2):
        combined = current_level[i] + current_level[i + 1]
        hash_combined = hashlib.sha256(
            combined.encode('utf-8')
        ).hexdigest()

        new_level.append(hash_combined)

    print(
        f" Combining {current_level[i][:6]}... and "
        f"{current_level[i + 1][:6]}... to get "
        f"{hash_combined[:6]}..."
    )

    current_level = new_level
    level += 1

# Final remaining hash is the Merkle Root
return current_level[0]

```

```
*** Initial Hashed Transactions: ['4d5a82f66fcc5af28031a82a5ceb39dc3fe23097c56c8dff7720841a02aef1f', 'fd0b9eafb0c7f54035c2f21ff45dbbf165440d59

Level 3 Hashes:
  Combining 6fa7f1... and ba86e9... to get c5db5f...

Merkle Root: c5db5fb4092cf71773baf667101b0158168f44d9a99579c5385353c80ef38aff
```

Conclusion:-

Cryptographic hash functions like **SHA-256** help keep blockchain data safe, secure, and unchangeable. **Merkle Trees** organize transactions in a way that makes it easy to verify them quickly and detect any tampering. Together, they make blockchain trustworthy, capable of handling large amounts of data without compromising security. These concepts help us understand how blockchain maintains security, efficiency even with large amounts of data.

Class:D20A

Roll No:38

Batch:B

Aim: Create a Blockchain using Python

1. What is Blockchain

Blockchain is a revolutionary technology that functions as a shared, immutable digital ledger, often described as a decentralized database or distributed ledger technology. It records transactions across a network of computers in a way that ensures security, transparency, and resistance to tampering. The term "blockchain" derives from its structure: data is organized into blocks, each linked to the previous one through cryptographic hashes, forming a continuous chain. This decentralized nature eliminates the need for intermediaries, allowing multiple parties to perform transactions without third-party intervention.

Key characteristics include:

- **Decentralization:** No single entity controls the network; it's maintained by nodes (computers) that validate and record transactions.
- **Immutability:** Once data is added, it cannot be altered without consensus from the network, making it tamper-proof.
- **Transparency:** All participants can view the ledger, but privacy is maintained through cryptography.
- **Security:** Uses cryptographic techniques to protect data.

Blockchain stores various types of information, but it's most commonly used for transactions in cryptocurrencies like Bitcoin. It operates on principles

such as consensus mechanisms to agree on the state of the ledger. Unlike traditional databases that structure data in tables, blockchain uses blocks chained together, ensuring that changes to one block would require altering all subsequent blocks, which is computationally infeasible

2. What is a Block?

A block is the fundamental building block of a blockchain, acting as a container for data such as transactions. It serves as a record in the digital ledger, similar to a page in a book, where each block holds a complete record of transactions or other information. Blocks are linked together in a chain, with each new block referencing the previous one via a cryptographic hash, creating an unbreakable sequence.

In essence, a block is a node in the blockchain network that stores encrypted data, including a list of transactions, a timestamp, and a unique identifier (hash). The first block in any blockchain is called the Genesis Block, which has no previous block reference and is hardcoded into the protocol. This structure ensures the integrity of the entire chain, as altering any block would invalidate the hashes of all following blocks

3. Components of a Block

A block in blockchain consists of two main parts: the block header and the block body (containing transactions). The header is crucial for identification and linking, while the body holds the actual data.

Key components include:

Component	Description
Block Header	Identifies the block and includes metadata like version, timestamp, Merkle root, difficulty target, nonce, and previous block hash.
Version	A 4-byte field tracking software or protocol upgrades.
Previous Block Hash	A 32-byte reference to the hash of the prior block, ensuring chain continuity.
Merkle Root	A 32-byte hash of all transactions in the block, derived from a Merkle tree for efficient verification.
Timestamp	A 4-byte record of the block's approximate creation time.
Difficulty Target	A 4-byte value setting the mining difficulty.
Nonce	A 4-byte number used in proof-of-work mining to find a valid hash.

Transactions	The list of verified transactions stored in the block body.
--------------	---

These elements work together to maintain security and enable validation. The header alone is often sufficient for light clients to verify blocks without the full data

4. Process of mining

Mining is the process of validating transactions and adding new blocks to the blockchain. It is primarily associated with **Proof-of-Work (PoW)** consensus mechanisms (e.g., Bitcoin). Miners compete to solve a complex cryptographic puzzle, and the winner gets to add the block and receive a reward.

Key steps in the mining process:

2. **Transaction Collection** Unconfirmed transactions are collected from the network and stored in a **mempool** (memory pool). Miners select

transactions (usually prioritizing those with higher fees) to include in a candidate block. A special **coinbase transaction** is added, which rewards the miner with new coins + transaction fees.

3. **Block Header Preparation** The miner constructs the block header, which includes:
 - Previous block hash
 - Merkle root (summary hash of all transactions)
 - Timestamp
 - Difficulty target
 - Nonce (a variable number starting from 0)
4. **Solving the Cryptographic Puzzle (Proof-of-Work)** Miners repeatedly hash the block header (using SHA-256 in Bitcoin) while changing the nonce value. The goal is to find a hash that is **less than or equal to the current difficulty target** (a very small number, often requiring the hash to start with many leading zeros). This is computationally intensive and probabilistic — miners try billions/trillions of nonces per second.
5. **Block Found** The first miner to find a valid nonce (producing a qualifying hash) has "solved" the puzzle. They broadcast the completed block to the network.
6. **Network Acceptance & Reward** Other nodes verify the block. If valid, it is added to their copy of the blockchain. The successful miner receives the **block reward** (e.g., currently 3.125 BTC as of recent halvings) + transaction fees. Difficulty adjusts periodically to keep average block time stable (~10 minutes in Bitcoin).

Mining secures the network by making it extremely expensive to alter past blocks (would require re-mining all subsequent blocks) and prevents double-spending.

5. Checking the validity of blocks in blockchain

Once a mined block is broadcast, every full node independently verifies it before accepting it into their blockchain copy. This decentralized validation is what makes blockchain trustless and secure.

Key validity checks:

- **Block Structure & Syntax**
 - Correct format and size
 - Valid version number
 - Timestamp is reasonable (not too far in future or before previous block)
- **Previous Block Hash Match** The "previous block hash" field must exactly match the hash of the most recent block already in the node's chain.

- **Proof-of-Work Validation** Recompute the block hash → check if it is $\leq$ current difficulty target (i.e., has enough leading zeros). This confirms the miner did the required work.
- **Merkle Root Verification** Rebuild the Merkle tree from all transactions in the block body → verify the computed Merkle root matches the one in the block header.
- **Transaction Validity**
 - Each transaction has valid signatures
 - Inputs are unspent (no double-spending)
 - **Input amounts $\geq$ output amounts + fees**
 - Transactions follow protocol rules
- **Consensus Rules Compliance** Block follows all network rules (max block size, valid coinbase, etc.).

If **any** check fails, the block is rejected and not added to the chain. Nodes continue waiting for a valid block. The longest valid chain (most cumulative work) is considered the true chain.

Light clients (SPV wallets) use simplified checks — they rely on **Merkle proofs** to confirm a transaction exists in a block without downloading everything.

Implementation:-

Installing Flask

```

Conclusion:-

In this experiment, a simple blockchain was successfully built using Python. It clearly illustrated the essential concepts of blockchain, such as block structure, cryptographic hashing, Proof-of-Work mining, and chain validation. Through hash-linked blocks and strict difficulty-based verification rules, the system guarantees data integrity, immutability, and strong resistance to tampering. Even a minor change in any block breaks the entire chain, perfectly showcasing the decentralized and secure foundation of blockchain technology.

CO2: Interpret the knowledge of the Bitcoin network, nodes, keys, wallets and transactions CO3: Implement smart contracts in Ethereum using different development frameworks. CO5: Interpret different Crypto assets and Crypto currencies

EXPERIMENT NO.3

Name:Aryan Anil Patankar

Class:D20A

Roll No:38

Batch:B

Aim: Create a Cryptocurrency using Python and perform mining in the Blockchain created.

1. Blockchain Overview

Blockchain is a **distributed and decentralized digital ledger** that records transactions across a network of computers (nodes) in a secure, transparent, and tamper-resistant manner. It eliminates the need for a central authority by using cryptography and consensus.

Data is stored in a series of linked **blocks** forming a chronological chain. Each block typically contains:

4. A list of **transaction data** (e.g., sender, receiver, amount)
5. A **timestamp** indicating when the block was created
6. The **hash of the previous block** (creating the link)
7. Its own **unique hash** (a cryptographic digital fingerprint generated from the block's contents)

Once a block is added to the chain and confirmed by the network, its data becomes **immutable** — changing any information in a block would alter its hash, breaking the link to the next block and requiring recalculation of all subsequent blocks (which is computationally infeasible in a large network). This structure ensures security, transparency, and trust without intermediaries.

2. Mining

Mining is the process of validating transactions, creating new blocks, and securing the blockchain through computational work, primarily using the **Proof-of-Work (PoW)** consensus mechanism (as in Bitcoin).

Steps in mining:

- Miners collect **pending transactions** from the network (mempool) and group them into a candidate block.
- They perform a **computational puzzle** — repeatedly hashing the block header (including a variable nonce) until the resulting hash meets the network's difficulty target (e.g., starts with a required number of leading zeros).
- The first miner to find a valid hash **adds the new block** to their copy of the blockchain and **broadcasts** it to all peers for verification.
- If accepted, the block becomes part of the official chain.

Successful miners receive a **reward** (newly minted cryptocurrency + transaction fees) as an incentive for their work. Mining prevents double-spending, maintains decentralization, and makes tampering extremely expensive.

3. Multi-Node Blockchain Network

In a real blockchain (and in this lab simulation), the network operates as a **peer-to-peer (P2P)** system with multiple independent **nodes** (computers) instead of a central server.

In the lab setup:

3. Three nodes run on separate ports (e.g., 5001, 5002, 5003).

4. Each node maintains its **own full copy** of the blockchain ledger.
5. Nodes communicate directly with each other (P2P) to share new blocks, transactions, and chain information.
6. This decentralization ensures no single point of failure — if one node goes offline, others continue operating and can sync later.

Nodes validate incoming data and propagate valid information across the network, enabling global consensus without trusting any central entity.

4. Consensus Mechanism

Consensus is the process by which all nodes in a decentralized network agree on the valid state of the blockchain (i.e., which chain and transactions are legitimate).

In this lab (and Bitcoin), the mechanism used is the **Longest Chain Rule** (also called Nakamoto Consensus in PoW systems):

- When multiple valid chains exist (e.g., due to near-simultaneous block mining), nodes always adopt the **longest valid chain** (the one with the most accumulated proof-of-work / blocks).
- This rule resolves conflicts automatically — shorter/forked chains are eventually discarded as miners continue building on the longest one.
- It ensures eventual agreement on a single transaction history across the entire network.

This simple yet powerful rule achieves reliable consensus in a trustless environment.

5. Transactions & Mining Reward

A **transaction** in blockchain is a record of value transfer between parties, typically including:

- **Sender** address
- **Receiver** address
- **Amount** transferred
- Digital signature (to prove ownership)

Transactions are collected in the mempool, verified, and included in blocks during mining.

When a miner successfully creates a new block:

- All selected pending transactions are added to the block body.
- An automatic **reward transaction** (coinbase transaction) is included as the first transaction in the block.
- This coinbase transaction pays the miner a fixed **block reward** (newly created coins) plus all **transaction fees** paid by users.

The reward incentivizes miners to secure the network and introduces new coins into circulation in a controlled manner.

6. Chain Replacement

In a decentralized network, nodes may temporarily have different chain versions due to network delays or simultaneous mining.

The **/replace_chain** endpoint (or equivalent resolve function) implements conflict resolution:

7. The node requests the current blockchain from all connected peers.

8. It compares the lengths (and validity) of received chains against its own.
9. If a **longer and valid chain** is found (following the longest chain rule), the node replaces its local chain with the longer one.
10. The node discards its shorter/forked chain and adopts the majority-accepted version.

This process keeps the blockchain synchronized and consistent across all nodes, ensuring everyone eventually agrees on the same transaction history.

OUTPUT:-

1. Connect Nodes (POST)

URL (from any node):

POST http://127.0.0.1:5001/connect_node

Body → raw → JSON

```
{  
  
  "nodes":  
  
  [  
  
    "http://127.0.0.1:5002",  
  
    "http://127.0.0.1:5003"  
  
  ]  
  
}
```

The screenshot shows a REST client interface with the following details:

- URL:** http://127.0.0.1:5001/connect_node
- Method:** POST
- Body Type:** raw (selected), JSON (available)
- Request Body (raw):**

```
{  
  "nodes":  
  [  
    "http://127.0.0.1:5002",  
    "http://127.0.0.1:5003"  
  ]  
}
```
- Response Status:** 201 CREATED (17 ms, 325 B)
- Response Body (JSON):**

```
{  
  "message": "All the nodes are now connected. The Hadcoin Blockchain now contains the following nodes:",  
  "total_nodes": [  
    "127.0.0.1:5003",  
    "127.0.0.1:5002"  
  ]  
}
```

2. Add Transaction (POST)

URL

POST `http://127.0.0.1:5001/add_transaction`

Body

```
{  
  
  "sender": "Aryan Patankar",  
  
  "receiver": "Vaishnal Mali",  
  
  "amount": 500  
}
```

Transaction goes into **mempool**, NOT block yet

3. Mine Block (GET)

GET http://127.0.0.1:5001/mine_block

4. Get Blockchain (GET)

GET `http://127.0.0.1:5001/get_chain`

You'll see:

- Transactions inside blocks
- transactions: [] for new pending list

blockchain / http://127.0.0.1:5001/get_chain

GET

5. Replace Chain (Consensus)

GET http://127.0.0.1:5002/replace_chain

Shorter chains get replaced by the longest valid one

CONCLUSION:

In this experiment, a simple cryptocurrency was successfully created using Python by implementing core blockchain concepts such as block creation, hashing, Proof-of-Work mining, transactions, and decentralization. The blockchain system was developed using Flask, allowing multiple nodes to communicate and maintain their own copies of the blockchain. Mining was performed by solving the Proof-of-Work algorithm, through which new blocks were added to the blockchain and miners were rewarded with cryptocurrency. The experiment also demonstrated transaction handling, where transactions were verified and included in mined blocks. Overall, this experiment

provided a practical understanding of how blockchain technology works, including mining, decentralization, and consensus, and highlighted how cryptocurrencies operate in real-world distributed systems.

Class	D20A
Subject	ITC801: Blockchain and DLT Lab
CO Mapped	CO3:Implement smart contracts in Ethereum using different development frameworks.

EXPERIMENT NO.4

Name:Aryan Anil Patankar

Class:D20A

Roll No:38

Batch:B

Aim:Hands on Solidity Programming Assignments for creating Smart Contracts

Theory:-

1. Primitive Data Types, Variables, Functions - pure, view

Primitive (Value) Data Types in Solidity include:

bool → true/false

int / uint (signed/unsigned integers, e.g., uint256 is most common)

address → 20-byte Ethereum address

bytes1 to bytes32 → fixed-size byte arrays

string → dynamic UTF-8 encoded text (reference type, but often grouped here)

Variables are declared with a type and can be:

State variables → stored permanently on the blockchain (expensive)

Local variables → exist only during function execution

Functions can be marked as:

pure → does not read or write state (computes only from inputs;
cheapest gas)

view → reads state but does not modify it (e.g., getters; no gas when called externally)

Example

```
function getResult() public view returns (uint product, uint sum) {  
    product = num1 * num2; // reads state  
    sum = num1 + num2;  
}
```

```
function pureCalc(uint a, uint b) public pure returns (uint) {  
    return a + b; // no state access  
}
```

2. Inputs and Outputs to Functions

Functions in Solidity can take **parameters** (inputs) and return **values** (outputs).

Inputs: Declared in parentheses; can use data locations like memory or calldata for reference types.

Outputs: Declared after returns keyword; can return multiple values.

Example:

```
function add(uint a, uint b) public pure returns (uint sum) {  
    sum = a + b;  
}
```

```
// Multiple outputs
```

```
function getValues() public view returns (uint, string memory) {  
    return (age, name);  
}
```

Use calldata for external calls (cheaper, read-only).

Use memory for temporary copies inside functions.

3. Visibility, Modifiers and Constructors

Visibility Specifiers (for functions and state variables):

- **public** → anyone can call/read (default for state vars creates getter)
- **private** → only inside current contract
- **internal** → current + derived (child) contracts
- **external** → only external calls (cheaper for large data)

Modifiers → reusable code blocks that run before/after function body (e.g., access control).

Use `_` to insert function body.

```
modifier onlyOwner() {  
    require(msg.sender == owner, "Not owner");  
    _;  
}
```

```
function restricted() public onlyOwner { ... }
```

Constructors → special function that runs once on deployment (initializes state).

- Syntax: `constructor() { ... }` (older: same name as contract)

4. Control Flow: if-else, loops

Solidity supports standard control structures:

if-else:

```
if (condition) {  
    // true  
} else if (another) {  
    // else-if  
} else {  
    // false  
}
```

Loops:

```
for (uint i = 0; i < 10; i++) { ... }  
while (condition) { ... }  
do { ... } while (condition);
```

Avoid unbounded loops (gas limit risk). Use `break` / `continue` when needed.

5. Data Structures: Arrays, Mappings, structs, enums

- **Arrays**
 - Fixed: `uint[5] arr;`

- Dynamic: uint[] arr; (use .push(), .pop(), .length)
- **Mappings** → key-value store (like hash table)
mapping(address => uint) public balances;

Keys can be most types; no iteration possible.

Structs → custom composite types

```
struct User {  
    address wallet;  
    uint balance;  
    bool active;  
}  
User public owner;
```

Enums → named constants (integers under the hood)

```
enum Status { Pending, Active, Cancelled }  
Status public state = Status.Pending;
```

6. Data Locations

Solidity has three main **data locations** for reference types (arrays, structs, mappings, strings):

storage → permanent blockchain storage (persistent, expensive) Default for state variables.

memory → temporary, function lifetime only (deleted after execution)
Cheap; used for local variables & function args/returns.

calldata → read-only, non-modifiable area for function call data
Cheapest for external function parameters (immutable copy of tx data).

Rule:

State vars → always storage

Function args → prefer calldata (external) or memory

Local reference vars → must specify location

7. Transactions: Ether and wei, Gas and Gas Price, Sending Transactions

8. **Ether units** → smallest is **wei** (1 ETH = 10^{18} wei) Other: gwei (10^9 wei), commonly used for gas prices.

9. **Gas** → computational effort unit

- **Gas Limit** → max gas willing to spend (set by sender)
- **Gas Price** → price per gas unit (in wei/gwei; set by sender)
- Total fee = gas used × gas price

10. **msg.value** → amount of wei sent with transaction

11. **Sending Ether** → use `.transfer()`, `.send()`, or `.call{value: amount}("")` (recommended low-level call)

Example:

```
function sendEther(address payable recipient) public payable {  
    recipient.transfer(msg.value);  
}
```

Use payable for addresses/functions that receive Ether.

tx.gasprice → current gas price (global var)

Implementation:-

Tutorial no. 1 – Compile the code

The screenshot displays the REMIX IDE interface. On the left, the 'SOLIDITY COMPILER' panel shows the compiler version '0.8.31+commit.fd3a2265' and options for 'Auto compile' and 'Hide warnings'. Below these are buttons for 'Compile introduction.sol', 'Compile and Run script', 'Run Remix Analysis', 'Run SolidityScan', 'Publish on IPFS', and 'Publish on Swarm'. The main editor on the right shows a Solidity contract named 'Counter' with functions 'get()', 'inc()', and 'dec()'. The 'get()' function is highlighted, showing a gas cost of 2453. The bottom status bar includes a 'Scam Alert' and a message: 'Did you know? You can verify your contract using the Etherscan plugin.'

2. Basic Syntax

2 / 19

variable when you declare it. In this case, `greet` is a `string`.

We also define the *visibility* of the variable, which specifies from where you can access it. In this case, it's a `public` variable that you can access from inside and outside the contract.

Don't worry if you didn't understand some concepts like *visibility*, *data types*, or *state variables*. We will look into them in the following sections.

To help you understand the code, we will link in all following sections to video tutorials from the [creator](#) of the Solidity by Example contracts.

[Watch a video tutorial on Basic Syntax.](#)

★ Assignment

- Delete the HelloWorld contract and its content.
- Create a new contract named "MyContract".
- The contract should have a public state variable called "name" of the type string.
- Assign the value "Alice" to your new variable.

3. Primitive Data Types

3 / 19

Later in the course, we will look at data structures like **Mappings**, **Arrays**, **Enums**, and **Structs**.

[Watch a video tutorial on Primitive Data Types.](#)

★ Assignment

- Create a new variable `newAddr` that is a `public` `address` and give it a value that is not the same as the available variable `addr`.
- Create a `public` variable called `neg` that is a negative number, decide upon the type.
- Create a new variable, `newU` that has the smallest `uint` size type and the smallest `uint` value and is `public`.

Tip: Look at the other address in the contract or search the internet for an Ethereum address.

5.2 Functions - View and Pure

6 / 19

the state variable `x`.

In Solidity development, you need to optimise your code for saving computation cost (gas cost). Declaring functions view and pure can save gas cost and make the code more readable and easier to maintain. Pure functions don't have any side effects and will always return the same result if you pass the same arguments.

[Watch a video tutorial on View and Pure Functions.](#)

★ Assignment

Create a function called `addToX2` that takes the parameter `y` and updates the state variable `x` with the sum of the parameter and the state variable `x`.

5.4 Functions - Inputs and Outputs

8 / 19

parameters of contract functions that are publicly visible. from the [Solidity documentation](#).

Arrays can be used as parameters, as shown in the function `arrayInput` (line 71). Arrays can also be used as return parameters as shown in the function `arrayOutput` (line 76).

You have to be cautious with arrays of arbitrary size because of their gas consumption. While a function using very large arrays as inputs might fail when the gas costs are too high, a function using a smaller array might still be able to execute.

[Watch a video tutorial on Function Outputs.](#)

★ Assignment

Create a new function called `returnTwo` that returns the values `-2` and `true` without using a return statement.

8.2 Data Structures - Mappings

13 / 19

with a key, which will set it to the default value of 0. As we have seen in the arrays section.

[Watch a video tutorial on Mappings.](#)

★ Assignment

1. Create a public mapping `balances` that associates the key type `address` with the value type `uint`.
2. Change the functions `get` and `remove` to work with the mapping `balances`.
3. Change the function `set` to create a new entry to the `balances` mapping, where the key is the address of the parameter and the value is the balance associated with the address of the parameter.

8.3 Data Structures - Structs

14 / 19

23).

Accessing structs

To access a member of a struct we can use the dot operator (line 33).

Updating structs

To update a structs' member we also use the dot operator and assign it a new value (lines 39 and 45).

[Watch a video tutorial on Structs.](#)

★ Assignment

Create a function `remove` that takes a `uint` as a parameter and deletes a struct member with the given index in the `todos` mapping.

8.4 Data Structures - Enums

15 / 19

and its member (line 35).

Removing an enum value

We can use the delete operator to delete the enum value of the variable, which means as for arrays and mappings, to set the default value to 0.

Watch a video tutorial on Enums.

★ Assignment

1. Define an enum type called `Size` with the members `S`, `M`, and `L`.
2. Initialize the variable `sizes` of the enum type `Size`.
3. Create a getter function `getSize()` that returns the value of the variable `sizes`.

9. Data Locations

16 / 19

to be careful in the beginning, when creating contracts we have to be mindful of gas costs. Therefore, we need to use data locations that require the lowest amount of gas possible.

★ Assignment

1. Change the value of the `myStruct` member `foo` inside the `function f` to 4.
2. Create a new struct `myMemStruct2` with the data location `memory` inside the `function f` and assign it the value of `myMemStruct`. Change the value of the `myMemStruct2` member `foo` to 1.
3. Create a new struct `myMemStruct3` with the data location `memory` inside the `function f` and assign it the value of `myStruct`. Change the value of the `myMemStruct3` member `foo` to 3.
4. Let the function `f` return `myStruct`, `myMemStruct2`, and `myMemStruct3`.

Tip: Make sure to create the correct return types for the function `f`.

10.1 Transactions - Ether and Wei

17 / 19

gwei

One `gwei` (giga-wei) is equal to 1,000,000,000 (10^9) `wei`.

ether

One `ether` is equal to 1,000,000,000,000,000,000 (10^{18}) `wei` (line 11).

[Watch a video tutorial on Ether and Wei.](#)

★ Assignment

- Create a `public uint` called `oneGwei` and set it to 1 `gwei`.
- Create a `public bool` called `isOneGwei` and set it to the result of a comparison operation between 1 `gwei` and 10^9 .

Tip: Look at how this is written for `gwei` and `ether` in the contract.

10.2 Transactions - Gas and Gas Price

18 / 19

Gas prices are denoted in gwei.

Gas limit

When sending a transaction, the sender specifies the maximum amount of gas that they are willing to pay for. If they set the limit too low, their transaction can run out of *gas* before being completed, reverting any changes being made. In this case, the *gas* was consumed and can't be refunded.

Learn more about *gas* on ethereum.org.

Watch a video tutorial on Gas and Gas Price.

★ Assignment

Create a new `public` state variable in the `Gas` contract called `cost` of the type `uint`. Store the value of the gas cost for deploying the contract in the new variable, including the cost for the value you are storing.

Tip: You can check in the Remix terminal the details of a transaction, including the gas cost. You can also use the Remix plugin *Gas Profiler* to check for the gas cost of transactions.

10.3 Transactions - Sending Ether

19 / 19

If you change the parameter type for the functions `sendViaTransfer` and `sendViaSend` (line 33 and 38) from `payable address` to `address`, you won't be able to use `transfer()` (line 35) or `send()` (line 41).

Watch a video tutorial on Sending Ether.

★ Assignment

Build a charity contract that receives Ether that can be withdrawn by a beneficiary.

- Create a contract called `Charity`.
- Add a public state variable called `owner` of the type `address`.
- Create a donate function that is public and payable without any parameters or function code.
- Create a withdraw function that is public and sends the total balance of the contract to the `owner` address.

Tip: Test your contract by deploying it from one account and then sending Ether to it from another account. Then execute the withdraw function.

Conclusion:-

Through this experiment, the fundamentals of Solidity programming were explored by completing practical assignments in the Remix IDE. Concepts such as data types, variables, functions, visibility, modifiers, constructors, control flow, data structures, and transactions were implemented and understood. The hands-on practice helped in designing, compiling, and deploying smart contracts on the Remix VM, thereby strengthening the understanding of blockchain concepts. This experiment provided a strong foundation for developing and managing smart contracts efficiently.

EXPERIMENT NO.5

Name:Aryan Anil Patankar

Class:D20A

Roll No:38

Batch:B

Aim:Deploying a Voting/Ballot Smart Contract

Theory:-

- **Relevance of require Statements in Solidity Programs**

In Solidity, the require statement acts as a **guard condition** within functions. It ensures that only valid inputs or authorized users can execute certain parts of the code. If the condition inside require is not satisfied, the function execution stops immediately, and all state changes made during that transaction are reverted to their original state. This rollback mechanism ensures that invalid transactions do not corrupt the blockchain data.

For example, in a **Voting Smart Contract**, require can be used to check:

- Whether the person calling the function has the right to vote (require(voters[msg.sender].weight > 0, "Has no right to vote");).
- Whether a voter has already voted before allowing them to vote again.
- Whether the function caller is the **chairperson** before granting voting rights.

Thus, require statements enforce **security, correctness, and reliability** in smart contracts. They also allow developers to attach error messages, making debugging and contract interaction easier for users.

- **Keywords: mapping, storage, and memory**

- **mapping:**

A mapping is a special data structure in Solidity that links keys to values, similar to a hash table. Its syntax is mapping(keyType => valueType). For example:

```
mapping(address => Voter) public voters;
```

Here, each address (Ethereum account) is mapped to a Voter structure. Mappings are very useful for contracts like **Ballot**, where you need to associate voters with their data (whether they voted, which proposal they chose, etc.). Unlike arrays, mappings do not have a length property and cannot be iterated over directly, making them **gas efficient** for lookups but limited for enumeration.

- **storage:**

In Solidity, storage refers to the **permanent memory** of the contract, stored on the Ethereum blockchain. Variables declared at the contract level are stored in storage by default. Data stored in storage is persistent across transactions, which means once written, it remains available unless explicitly modified. However, because writing to blockchain storage consumes gas, it is more expensive. For example, a voter's information saved in the voters mapping remains available throughout the contract's lifecycle.

- **memory:**

In contrast, memory is **temporary storage**, used only for the lifetime of a function call. When the function execution ends, the data stored in memory is discarded. Memory is mainly used for temporary variables, function arguments, or computations that don't need to be permanently stored on the blockchain. It is cheaper than storage in terms of gas cost. For instance, when handling proposal names or temporary string manipulations, memory is often used.

Thus, a smart contract developer must **balance between storage and memory** to ensure efficiency and cost-effectiveness.

- **Why bytes32 Instead of string?**

In earlier implementations of the Ballot contract, bytes32 was used for proposal names instead of string. The reason lies in **efficiency and gas optimization**.

- **bytes32** is a **fixed-size type**, meaning it always stores exactly 32 bytes of data. This makes storage simple, comparison operations faster, and gas costs lower. However, it limits proposal names to 32 characters, which is not very flexible for user-friendly names.
- **string** is a **dynamically sized type**, meaning it can store text of variable length. While it is easier for developers and users (since names can be written normally), it requires more complex handling inside the Ethereum Virtual Machine (EVM). This increases gas usage and may slow down comparisons or manipulations.

To make the system more user-friendly, modern implementations of the Ballot contract often convert from bytes32 to string. Tools like the **Web3 Type Converter** help developers easily switch between these two types for deployment and testing.

In summary, bytes32 is used when performance and gas efficiency are priorities, while string is preferred for readability and ease of use.

- **Code:**

```
// SPDX-License-Identifier: GPL-3.0

pragma solidity >=0.7.0 <0.9.0;

/**
 * @title Ballot
 * @dev Implements voting process along with vote delegation
 */
contract Ballot {
    // This declares a new complex type which will
    // be used for variables later.
    // It will represent a single voter.
    struct Voter {
        uint weight; // weight is accumulated by delegation
        bool voted;  // if true, that person already voted
        address delegate; // person delegated to
        uint vote;   // index of the voted proposal
    }

    // This is a type for a single proposal.
    struct Proposal
    {
        string name;    // Changed from bytes32 to string
        uint voteCount;
    }
    address public chairperson;

    // This declares a state variable that
    // stores a 'Voter' struct for each possible address.
    mapping(address => Voter) public voters;

    // A dynamically-sized array of 'Proposal' structs.
    Proposal[] public proposals;

    /**
     * @dev Create a new ballot to choose one of 'proposalNames'.
     * @param proposalNames names of proposals
     */
    constructor(string[] memory proposalNames) { // Changed bytes32[] to string[]
        chairperson = msg.sender;
        voters[chairperson].weight = 1;
        for (uint i = 0; i < proposalNames.length; i++) {
```

```

        proposals.push(Proposal({
            name: proposalNames[i],
            voteCount: 0
        }));
    }
}

/**
 * @dev Give 'voter' the right to vote on this ballot. May only be called by

        if (proposals[p].voteCount > winningVoteCount) {
            winningVoteCount = proposals[p].voteCount;
            winningProposal_ = p;
        }
    }
}

/**
 * @dev Calls winningProposal() function to get the index of the winner
contained in the proposals array and then
 * @return winnerName_ the name of the winner
 */
function winnerName() external view
    returns (string memory winnerName_)
{
    winnerName_ = proposals[winningProposal()].name;
}
}

```

Output:-

1)Compile the Ballot.sol Contract

The screenshot displays the Solidity Compiler interface within the Remix IDE. The left sidebar contains configuration options and a list of actions for the 'Ballot (3_Ballot.sol)' contract, including 'Compile 3_Ballot.sol', 'Compile and Run script', 'Run Remix Analysis', 'Run SolidityScan', 'Publish on IPFS', 'Publish on Swarm', and 'Compilation Details'. The main area shows the 'Ballot' contract's metadata, including compiler settings (Solidity, version 1) and the generated bytecode. The bottom panel shows a terminal window with a welcome message and instructions for using the command line interface.

2)Deploying and running of the contract

The screenshot shows the Remix IDE interface. On the left, the 'DEPLOY & RUN TRANSACTIONS' panel is active. It displays the contract name 'Ballot - contracts/3_Ballot.sol' and the EVM version 'osaka'. The 'Deploy' button is highlighted. Below it, the 'At Address' button is visible. The 'GAS LIMIT' is set to 'Estimated Gas' with a value of 3000000. The 'VALUE' is set to 0 Wei. The 'Transactions recorded' section shows 1 transaction. The 'Deployed Contracts' section shows 1 contract deployed at address 0xD91...39138.

The main editor shows the Solidity code for the 'Ballot' contract. The code includes a constructor and a 'winnerName()' function. The constructor takes two arguments, 'Aryan Patankar' and 'Vaishnal', and sets the 'winnerName_' variable to 'proposals[winningProposal()].name;'. The 'winnerName()' function is an external view function that returns the 'winnerName_' variable.

The 'Explain contract' panel at the bottom shows the transaction details for the deployment. It indicates that the transaction was successful and provides the transaction hash, block hash, block number, and contract address.

3>Loading the proposal candidate's name(string)

The screenshot shows the Remix IDE interface. On the left, the 'DEPLOY & RUN TRANSACTIONS' panel is active. It displays the contract name 'Ballot - contracts/3_Ballot.sol' and the EVM version 'osaka'. The 'Deploy' button is highlighted. Below it, the 'At Address' button is visible. The 'GAS LIMIT' is set to 'Estimated Gas' with a value of 3000000. The 'VALUE' is set to 0 Wei. The 'Transactions recorded' section shows 1 transaction. The 'Deployed Contracts' section shows 1 contract deployed at address 0xD91...39138.

The main editor shows the Solidity code for the 'Ballot' contract. The code includes a constructor and a 'winningProposal()' function. The 'winningProposal()' function is a public view function that returns the 'winningProposal_' variable. The function iterates through the 'proposals' array and returns the index of the winning proposal.

The 'Explain contract' panel at the bottom shows the transaction details for the execution of the 'winningProposal()' function. It indicates that the transaction was successful and provides the transaction hash, block hash, block number, and contract address. The 'decoded input' section shows the input arguments for the function, which are the names of the proposal candidates: 'Aryan Patankar', 'Vaishnal', and 'Niraj'.

4) Viewing the details of the Proposal Candidate

5) Giving the right to an account other than and by the chairman

The screenshot shows the Remix IDE interface. On the left, the 'DEPLOY & RUN TRANSACTIONS' panel is active, displaying the 'BALLED AT 0XD91...39138 (MEMORY)' contract. The 'Balance: 0 ETH' is shown. The 'delegate' field is set to 'address to'. The 'giveRightToVote' field is set to '0xAb8483F64d9C6d1EcF9b849Ae677dD33'. The 'vote' field is set to 'uint256 proposal'. The 'chairperson' field is set to '0: address: 0x5B38Da6a701c56854dCfc803FcB875f56beddC4'. The 'proposals' field is set to '0'. The 'voters' field is set to 'address'. The 'winnerName' and 'winningProposal' fields are empty. The 'Transact' button is visible at the bottom.

On the right, the 'Solidity Compile Details' panel shows the compiled code for '3_Ballot.sol'. The code includes a function `winningProposal()` that returns the winning proposal index. Below the code, the 'Explain contract' panel displays the transaction details for the 'giveRightToVote' function call.

Transaction details:

- status: 1 Transaction mined and execution succeed
- transaction hash: 0xc939ce8f8b5336f86beda71feaa691ecbe80c8c8cc6821958f8bcbe88556d6
- block hash: 0x57dc15c9fa967d85463781d80e27e3e069666fd1613041285d6674a59fc85c25
- block number: 2
- from: 0x5B38Da6a701c56854dCfc803Fc875f56beddC4
- to: Ballot.giveRightToVote(address) 0xd9145CCE520386f254917e481e844e9943f39138
- transaction cost: 48642 gas
- execution cost: 27210 gas
- output: 0x
- decoded input: { "address voter": "0xAb8483F64d9C6d1EcF9b849Ae677dD3315835cb2" }

6) Selecting the account which was given the right to vote and then writing the proposal candidate's index to vote.

The screenshot shows the Remix IDE interface. On the left, the 'DEPLOY & RUN TRANSACTIONS' panel is active, displaying the 'BALLED AT 0XD91...39138 (MEMORY)' contract. The 'Balance: 0 ETH' is shown. The 'delegate' field is set to 'address to'. The 'giveRightToVote' field is set to '0xAb8483F64d9C6d1EcF9b849Ae677dD33'. The 'vote' field is set to '0'. The 'chairperson' field is set to '0: address: 0x5B38Da6a701c56854dCfc803FcB875f56beddC4'. The 'proposals' field is set to '0'. The 'voters' field is set to 'address'. The 'winnerName' and 'winningProposal' fields are empty. The 'Transact' button is visible at the bottom.

On the right, the 'Solidity Compile Details' panel shows the compiled code for '3_Ballot.sol'. The code includes a function `winningProposal()` that returns the winning proposal index. Below the code, the 'Explain contract' panel displays the transaction details for the 'vote' function call.

Transaction details:

- status: 1 Transaction mined and execution succeed
- transaction hash: 0xc66880f36854abf57f4f875a36b5bfafae3fa7c2716055cd6470628a9a2d2510
- block hash: 0x60889ae631b336a186dd93ba5086887857f2064e5cb2c66957609df9f28f98db
- block number: 3
- from: 0xAb8483F64d9C6d1EcF9b849Ae677dD3315835cb2
- to: Ballot.vote(uint256) 0xd9145CCE520386f254917e481e844e9943f39138
- transaction cost: 72984 gas

7) We can view the Voter's Information

The screenshot displays a web interface with a sidebar on the left and a main content area on the right. The sidebar has a 'voters' tab selected, showing a list of voters with details like '0: uint256: weight 1', '1: bool: voted true', '2: address: delegate 0x00', and '3: uint256: vote 0'. Below this, there are buttons for 'winnerName' and 'winningProposal', and a 'Transact' button. The main content area shows a transaction status: 'transact to Ballot.vote pending ...'. It includes a green checkmark icon and a message: '[vm] from: 0xAb8...35cb2 to: Ballot.vote(uint256) 0xd91...39138 value: 0 wei data: 0x012...00000 logs: 0 hash: 0xc66...d2510'. Below this, there is a table of transaction details: status (1 Transaction mined and execution succeed), transaction hash (0xc66880f36854abf57f4f875a36b5bfafae3fa7c2716655cd6470628a9a2d2510), block hash (0x60889ae631b336a186dd93ba5086887857f2064e5cb2c66957609df9f28f98db), block number (3), from (0xAb8483f64d9c6d1ecf9b849ae677d03315835cb2), to (Ballot.vote(uint256) 0xd9145CCE52D386f254917e481e844e9943f39138), transaction cost (72984 gas), execution cost (51792 gas), and output (Rx).

8) Selecting the account of the delegator and then writing the address of the voter to be delegated to.

The screenshot displays a web interface with a sidebar on the left and a main content area on the right. The sidebar has a 'DEPLOY & RUN TRANSACTIONS' section with a 'Remix VM (Cancel)' button. Below this, there is an 'ACCOUNT' section with a dropdown menu showing '0xAb8...35cb2 (99.999999999999748988)'. There is also a 'GAS LIMIT' section with 'Estimated Gas' selected and a value of '3000000'. The 'VALUE' section shows '0 Wei'. The 'CONTRACT' section shows 'Ballot - contracts/3_Ballot.sol' and a 'Deploy' button. The main content area shows a code editor with Solidity code for a 'winningProposal' function. Below the code editor, there is a table of transaction details: block number (7), from (0x4B20993Bc481177ec7E8f571ceCaEBA9e22C02db), to (Ballot.delegate(address) 0xd9145CCE52D386f254917e481e844e9943f39138), transaction cost (61199 gas), execution cost (39767 gas), output (0x), decoded input ({}), decoded output ({}), logs ([]), raw logs ([]), and a message: 'transact to Ballot.vote pending ...'.

9) Proposal Candidate's Information before giving the Delegate's vote

proposals

0

0: string: name Aryan Patankar

1: uint256: voteCount 3

10) In this final screenshot we can see that after the delegation's vote the weight of one vote of the one voter who was delegated is the number of people who delegated the voter as their voter (Default weight of any voter is 1)

The screenshot displays the Remix IDE interface during a smart contract transaction. On the left, the 'voters' array is updated with a new entry: {0: 'string: name Aryan Patankar', 1: 'uint256: voteCount 3', 2: 'address: delegate 0x00000000000000000000000000000000', 3: 'uint256: vote 0'}. The main editor shows the Solidity code for the 'winningProposal()' function. The right sidebar shows the 'Decoded input' and 'Decoded output' for the transaction, with the output being a JSON object: {\"0\": \"string: name Aryan Patankar\", \"1\": \"uint256: voteCount 3\"}. The bottom of the right sidebar shows the transaction details, including the 'call' data: [call] from: 0x58380a6a701c568545dCfc803Fc8875f56beddC4 to: Ballot.winningProposal() data: 0x609...ff1bd.

Conclusion:-

In this experiment, a Voting/Ballot smart contract was deployed using Solidity on the Remix IDE. The concepts of require statements, mapping, and data location specifiers like storage and memory were explored to understand their role in ensuring security, efficiency, and correctness in smart contracts. The difference between using bytes32 and string for proposal names was also studied, highlighting the trade-off between gas efficiency and readability. Overall, the experiment provided practical insights into the design and deployment of voting contracts on the blockchain.

EXPERIMENT NO.6

Name:Aryan Anil Patankar

Class:D20A

Roll No:38

Batch:B

Aim:Creating Smart Contracts and performing transactions using Solidity and Remix IDE

Theory:

A Smart Contract is a self-executing program stored on the blockchain that automatically enforces the terms of an agreement when predefined conditions are met. It eliminates the need for intermediaries, ensuring transparency, security, and trust between parties. Smart contracts are written in Solidity (for Ethereum-based systems) and executed on the Ethereum Virtual Machine (EVM).

Significance of Smart Contracts in the Ethereum Blockchain:

- **Automation:** Executes actions automatically when conditions are satisfied.
- **Transparency:** The contract code and transactions are visible on the blockchain.
- **Security:** Once deployed, contracts are immutable and tamper-proof.
- **Cost-effective:** Removes intermediaries and reduces transaction costs.
- **Trustless System:** Participants can interact without needing to trust each other directly.

Smart contracts form the backbone of decentralized applications (DApps) and decentralized finance (DeFi) systems on Ethereum.

Implementation:

The project “**Land Ownership Registry System**” focuses on automating land records and ownership transfers using Ethereum-based Smart Contracts.

To ensure the system works, we will implement two primary contracts:

12.**LandRegistry.sol:** Manages the database of lands and their owners.

13.LandTransfer.sol: Handles the logic of transferring ownership from a Seller to a Buyer.

Code:-

1. LandRegistry.sol

```
// SPDX-License-Identifier: MIT
pragma solidity ^0.8.0;

contract LandRegistry {
    struct Land {
        uint id;
        string location;
        uint area;
        address owner;
        bool isRegistered;
    }

    mapping(uint => Land) public lands;
    address public admin;

    constructor() {
        admin = msg.sender;
    }

    function registerLand(uint _id, string memory _location, uint _area, address _owner)
    public {
        require(msg.sender == admin, "Only admin can register land");
        require(!lands[_id].isRegistered, "Land already registered");

        lands[_id] = Land(_id, _location, _area, _owner, true);
    }

    function updateOwner(uint _id, address _newOwner) public {
        // This function will be called by the Transfer contract
        lands[_id].owner = _newOwner;
    }
}
```

```

    }

    function getLand(uint _id) public view returns (uint, string memory, uint, address) {
        Land memory l = lands[_id];
        return (l.id, l.location, l.area, l.owner);
    }
}

```

2.LandTransfer.sol

```

// SPDX-License-Identifier: MIT
pragma solidity ^0.8.0;

import "./LandRegistry.sol";

contract LandTransfer {
    LandRegistry public registry;

    constructor(address _registryAddress) {
        registry = LandRegistry(_registryAddress);
    }

    function transferOwnership(uint _landId, address _newOwner) public {
        (,, address currentOwner) = registry.getLand(_landId);

        require(msg.sender == currentOwner, "Only the owner can sell this land");

        registry.updateOwner(_landId, _newOwner);
    }
}

```

Step 1: Set up the Files

- Go to Remix IDE.
- In the File Explorer, create a new folder named LandRegistryProject.
- Create two files: LandRegistry.sol and LandTransfer.sol.

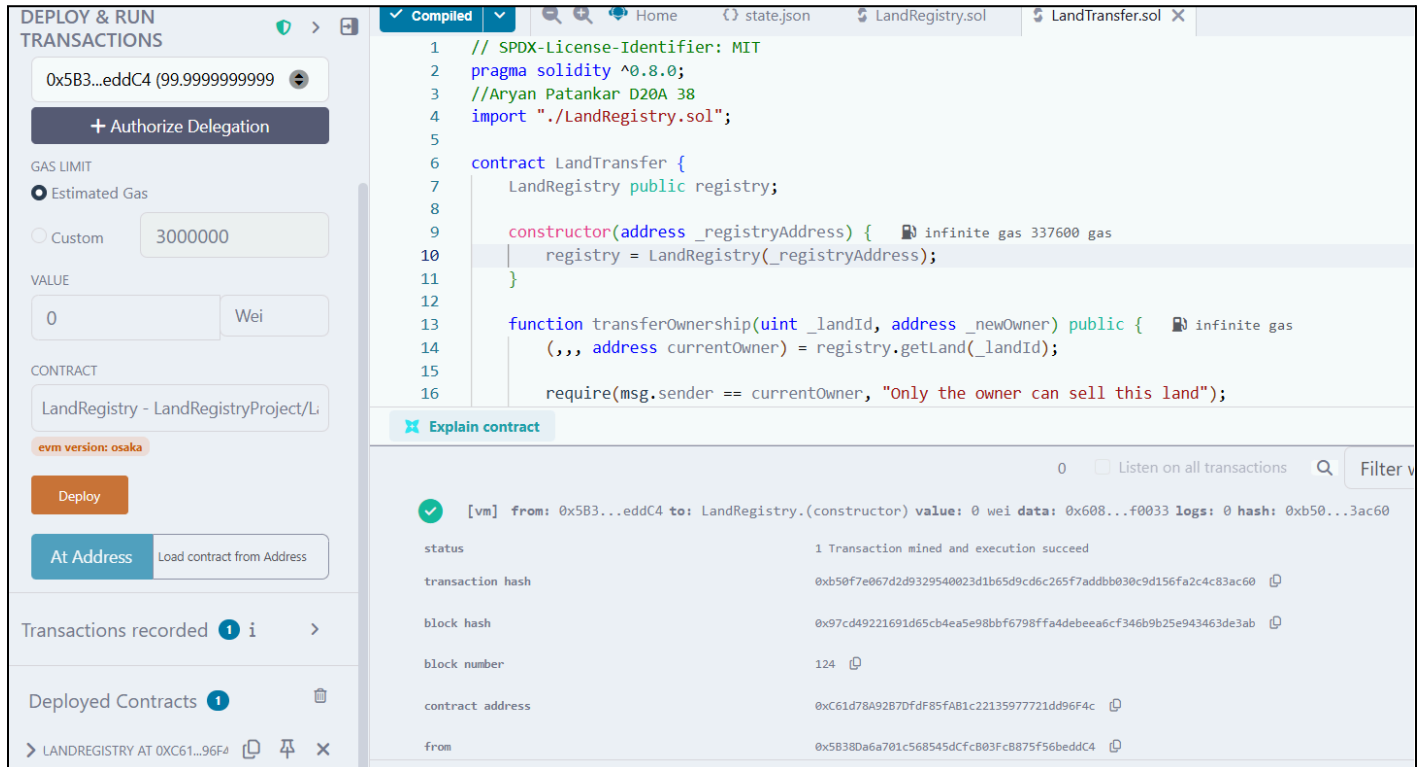

Step 2: Compile both the contracts

Step 3: Deploy the LandRegistry contract

Step 4: Copy the contract address of the deployed LandRegistry contract

15
16

require(msg.sender == currentOwner, "Only the owner can sell this land");

Conclusion:-

This experiment helped in understanding how smart contracts automate processes and execute securely on the Ethereum blockchain. Using Solidity and Remix IDE, the development, deployment, and interaction with smart contracts become simple and efficient, forming the foundation for decentralized applications.

Experiment 07

Aim: Implement the embedding wallet (Metamask) and transaction using Solidity

CO5:Interpret different Crypto assets and Crypto currencies

EXPERIMENT NO.7

Name:Aryan Anil Patankar

Class:D20A

Roll No:38

Batch:B

Aim:Implement the embedding wallet (Metamask) and transaction using Solidity

Theory:

1. What is MetaMask?

MetaMask is a software cryptocurrency wallet used to interact with the Ethereum blockchain and other EVM-compatible networks (like Polygon, BSC, and Avalanche).

It is primarily known as a "**bridge**" because it allows users to access Decentralized Applications (dApps) directly through a regular web browser (like Chrome or Firefox) without having to run a full Ethereum node.

Core Theoretical Functions:

14. **Identity Management:** It generates and manages your private keys locally on your device (not on a central server), giving you full ownership of your digital identity.
15. **Web3 Injection:** It injects a JavaScript library called **web3.js** or **ethers.js** into the websites you visit. This allows the website to "talk" to the blockchain.
16. **Transaction Signing:** When you want to perform an action on a dApp (like buying an NFT), MetaMask "pops up" to let you review and digitally sign the transaction before it is sent to the network.
17. **Network Switching:** It allows users to switch between the "Mainnet" (real money) and various "Testnets" (fake money).

2. What is a Testnet?

A **Testnet** (Test Network) is an alternative blockchain that acts as an exact replica of the main blockchain (Mainnet) but is used specifically for **experimenting, testing, and debugging**.

In blockchain theory, deploying code directly to the Mainnet is risky and expensive because every transaction costs real money (Gas fees) and bugs can lead to permanent financial loss. Testnets solve this by providing a "sandbox" environment.

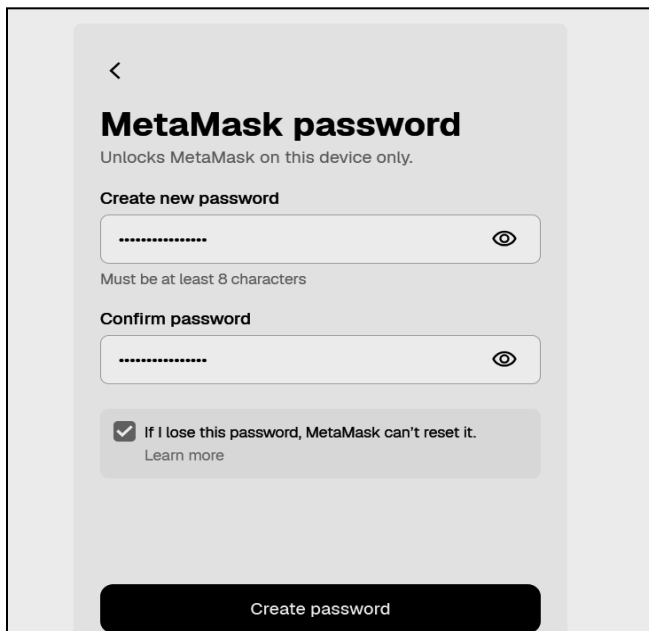

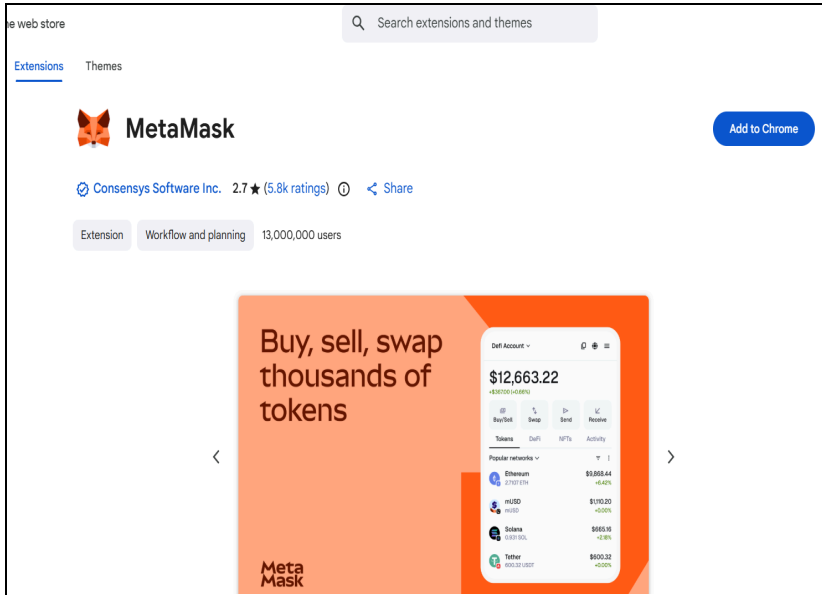

Key Characteristics:

- **No Real Value:** The tokens used on a testnet (e.g., Sepolia ETH) have **zero real-world market value**. You can get them for free from "Faucets."
- **Identical Environment:** It uses the same rules, consensus mechanisms (like Proof of Stake), and smart contract logic as the Mainnet.
- **Safe Playground:** If a developer's smart contract has a bug that crashes the system or "leaks" funds, no real money is lost.
- **Public Access:** Most testnets are public, meaning anyone can join and test their applications before the official launch.

Implementation:

Step 1: Install Metamask

Follow this [link](#) to install the Metamask Google Chrome Extension, and also create the wallet

Note :

- While creation of the Metamask Wallet, you will be asked to select 12 pass phrase
- Keep the passphrase safely
- It becomes handy to recover your password

Step 2: Enable Test Networks

- By default, MetaMask shows the "Ethereum Mainnet" (real money).
- Click the network dropdown (top left) and toggle **Show test networks**.
- Select **Sepolia**.

Step 3: Configuring the Sepolia Test network

The screenshot shows the MetaMask mobile application interface for configuring a new network. The title bar at the top is purple with the MetaMask logo and the word "MetaMask". Below this, a white modal window is titled "Sepolia" with a back arrow on the left and a close "X" on the right. The modal contains several configuration fields:

- Network name:** A text input field containing the word "Sepolia".
- Default RPC URL:** A dropdown menu showing "Infura" with the URL "sepolia.infura.io" below it and a downward arrow on the right.
- Chain ID:** A text input field containing the number "11155111".
- Currency symbol:** A text input field containing "SepoliaETH".
- Block explorer URL:** A dropdown menu showing "sepolia.etherscan.io" with a downward arrow on the right.

At the bottom of the modal is a large black button with the word "Save" in white text.

Step 4: Funding the Wallet

Every action on the blockchain requires a fee called **Gas**. On the Sepolia network, we use "Test ETH" which is free.

8. **Copy Your Address:** Click your account name at the top of MetaMask (it starts with `0x...`) to copy your public address.

2. **Visit a Faucet:** Use the [Google Cloud Sepolia Faucet](#) to procure SepoliaETH by pasting the wallet address as shown

3. **Verify:** Your MetaMask balance should update within 30 seconds.

Step 5: Connect MetaMask to Remix IDE

12. Open [Remix IDE](#).
13. Go to the **Deploy & Run Transactions** tab.
14. In the **Environment** dropdown, select **Injected Provider - MetaMask**.

A MetaMask popup will appear; click **Connect** to link your `0x7D11 . . .` account to Remix.

Step 6: Create and Compile the Contract

- Open your **LandRegistry.sol** file.
- Go to the **Solidity Compiler** tab.
- Select Compiler **0.8.0** (or the version in your code).
- Click **Compile LandRegistry.sol**.

Step 7: Deploy and Verify the transaction

- Go back to the **Deploy & Run Transactions** tab.
- Ensure **Injected Provider** is still selected (you should see "Custom (11155111) network").
- Click the orange **Deploy** button.
- **MetaMask Action:** A popup will show the gas fee. Click **Confirm**.
- **Wait:** Look at the bottom terminal. Wait for the green checkmark that says "transacted."

Conclusion:-

This experiment helped in understanding how smart contracts automate processes and execute securely on the Ethereum blockchain. Using Solidity and Remix IDE, the development, deployment, and interaction with smart contracts become simple and efficient, forming the foundation for decentralized applications.

ITC801 : Blockchain & DLT Lab

Experiment 08

Aim: To implement the Blockchain platform Ganache and deploy a simple Solidity smart contract using Metamask and Remix IDE.

Roll No.	38
Name	Aryan Patankar
Class	D20A
Subject	ITC801: Blockchain and DLT Lab
CO Mapped	CO2:Interpret the knowledge of the Bitcoin network, nodes, keys, wallets and transactions CO3:Implement smart contracts in Ethereum using different development frameworks. CO5:Interpret different Crypto assets and Crypto currencies

EXPERIMENT NO.8

Name:Aryan Anil Patankar

Class:D20A

Roll No:38

Batch:B

Aim: To implement the Blockchain platform Ganache and deploy a simple Solidity smart contract using Metamask and Remix IDE.

Theory:

1. Introduction to Blockchain

Blockchain is a distributed, decentralized digital ledger that records transactions across multiple nodes in a network. Each transaction is stored in a block, and blocks are linked together using cryptographic hashes, forming a secure and immutable chain.

Key features:

Decentralization – No central authority controls the system

Immutability – Data cannot be altered once recorded

Transparency – Transactions are visible to all participants

Security – Uses cryptographic techniques

2. What is Ganache?

Ganache is a personal blockchain simulator used for developing, testing, and debugging Ethereum-based decentralized applications (DApps).

It is part of the Truffle Suite, which provides tools for smart contract development.

Ganache creates a local blockchain environment that mimics the behavior of the real Ethereum network.

3. Features of Ganache

a. Local Blockchain

Ganache runs a blockchain locally on your system, allowing developers to test without using real cryptocurrency.

b. Pre-funded Accounts

Provides multiple accounts with preloaded Ether
Useful for testing transactions without cost

c. Instant Mining

- 15. Transactions are mined instantly
- 16. No waiting time like real networks

d. Detailed Transaction Logs

- 4. Displays:
 - Transaction hash
 - Gas usage
 - Block number
 - Events

e. Smart Contract Testing

Supports deployment and testing of smart contracts written in Solidity.

f. Customizable Settings

- Gas limit
- Gas price
- Number of accounts
- Network ID

4. Architecture of Ganache

Ganache simulates the Ethereum architecture:

a. Accounts Layer

- Contains multiple Ethereum accounts
- Each account has:
 - Address
 - Private key
 - Balance

b. Blockchain Layer

- Stores blocks and transactions
- Each block contains:
 - Block number
 - Timestamp
 - Transactions

c. Virtual Machine

Ganache uses the **Ethereum Virtual Machine** to execute smart contracts.

d. RPC Server

18. Provides JSON-RPC API
19. Allows interaction using tools like Web3.js

5. Working of Ganache

Ganache starts a local blockchain network
It generates multiple accounts with Ether
Developers deploy smart contracts
Transactions are executed
Ganache mines blocks instantly
Results are displayed in logs

6. Advantages of Using Ganache

No real Ether required
Faster testing (instant mining)
Easy debugging with detailed logs
Safe environment (no risk of real loss)
Ideal for beginners and developers

7. Limitations of Ganache

Not a real decentralized network
Does not simulate real-world latency
Limited scalability testing
Not suitable for production deployment

8. Applications of Ganache

- Smart contract development
- Testing decentralized applications (DApps)
- Learning Ethereum blockchain concepts

- Debugging transactions

Implementation:-

1. Set Up Ganache (The Local Blockchain)

- **Download & Install:** Go to the [Truffle Suite website](https://trufflesuite.com/ganache/) and install Ganache.

- **Launch:** Open Ganache and select "Quickstart".

- **Identify Details:** You will see a list of 10 addresses, each with 100 ETH.
 - Look at the top bar for **RPC Server**. It usually says **HTTP://127.0.0.1:7545**.
 - Look at the **Network ID**. It is usually **5777**.

2. Connect Ganache to MetaMask

MetaMask doesn't know about your local Ganache "server" yet, so we have to add it manually.

9. Open **MetaMask** -> Click the **Network Dropdown** (top left) -> **Add Network**.
10. Select **"Add a network manually"** at the bottom.
11. Enter these details:
 - **Network Name:** Localhost 8545
 - **New RPC URL:** **http://127.0.0.1:7545**
 - **Chain ID:** **1377**

- **Currency Symbol:** ETH

<
Add a custom network
X

Network name

Localhost 8545

Default RPC URL

Ganache RPC
127.0.0.1:7545

Chain ID

1337

Currency symbol

ETH

12. **Import Account:**

- In Ganache, click the **Key Icon** on the far right of the first address.

ADDRESS	BALANCE	TX COUNT	INDEX	
0x7110a5Ed96696D2FAA63C5F84f69Fc71B984DBfd	100.00 ETH	0	0	

- Copy the **Private Key**.

ACCOUNT ADDRESS

0x7110a5Ed96696D2FAA63C5F84f69Fc71B984DBfd

PRIVATE KEY

0xf4a7a11cb7e2aa839bae7d439672da8684ee9d061f2b809eb0c0da4700e845

- In MetaMask, click the Account Circle -> **Import Account** -> Paste the Private Key.

The screenshot shows the MetaMask application window with the title bar 'MetaMask'. Inside, the 'Add wallet' screen is displayed. At the top left is a back arrow, and at the top center is the title 'Add wallet'. Below this, the section 'Private key' is highlighted. The text explains that imported private keys are backed up to the account and sync automatically. A link 'Learn more about how imported keys work' is provided. Under 'Select type', a dropdown menu shows 'Private key' with a downward arrow. Below this, the prompt 'Enter your private key string here:' is followed by a text input field containing a series of dots and a toggle icon. At the bottom, there are two buttons: 'Cancel' and 'Import'.

- You should now see **100 ETH** in MetaMask!

3. Connect Remix to MetaMask (Injected Provider)

In Remix, go to the **Deploy & Run Transactions** tab.
Set **Environment** to **Injected Provider - MetaMask**.

MetaMask will ask to connect to "Ganache Local." Click **Confirm**.

4. Compile and Deploy

Compile your **LandRegistry.sol**.
In the Deploy tab, click **Deploy**.

Conclusion:-

The experiment successfully demonstrated the deployment of a **LandRegistry** smart contract on a local blockchain using Ganache, MetaMask, and Remix IDE. By configuring a custom RPC network and aligning the Chain ID, a secure bridge was established to authorize a pre-funded account for transaction gas. This process verified the contract's compilation and its successful migration to a private ledger, confirming the integrity of the decentralized data storage. The setup provides a cost-effective, local environment for testing full-scale blockchain application logic.

ITC801 : Blockchain & DLT Lab

Experiment 09

Aim: To implement a Private Ethereum Blockchain using Geth.

Roll No.	38
Name	Aryan Patankar
Class	D20A
Subject	ITC801: Blockchain and DLT Lab
CO Mapped	CO3:Implement smart contracts in Ethereum using different development frameworks.

EXPERIMENT NO.9

Name:Aryan Anil Patankar

Class:D20A

Roll No:38

Batch:B

Aim: To implement a Private Ethereum Blockchain using Geth.

Theory:

Ethereum is an open-source, decentralized blockchain platform that enables developers to build and deploy **smart contracts** and **decentralized applications (DApps)**. Unlike public blockchains such as the Ethereum mainnet, a **Private Ethereum Blockchain** is restricted to specific participants, making it ideal for **development, testing, and enterprise applications** where confidentiality, control, and performance are essential.

Geth (Go-Ethereum) is one of the most widely used Ethereum clients, written in the Go programming language. It allows users to run an Ethereum node, mine Ether, and interact with the blockchain through **JSON-RPC, command-line, or JavaScript consoles**.

Setting up a **Private Ethereum Network** involves creating a customized blockchain environment isolated from the public Ethereum network. It enables developers to test smart contracts, consensus mechanisms, and network behavior without incurring gas costs or depending on public validators.

Steps Involved:

- **Choosing a Network ID:**
- Each private blockchain must have a unique network ID to differentiate it from public or other private networks.
- **Choosing a Consensus Algorithm:**

- Ethereum supports different consensus mechanisms such as **Proof of Work (PoW)** and **Proof of Authority (PoA)**. In private networks, **Clique (PoA)** is often used for faster block confirmation.
- **Creating a Genesis Block:**
- The genesis block is the first block of the blockchain, defining network parameters such as difficulty, gas limit, initial account balances, and consensus settings.
- **Initializing the Geth Database:**
- The `geth init` command initializes the blockchain using the `genesis.json` file, preparing the data directory for node operation.
- **Setting up Networking:**
- Nodes communicate using **enodes** (Ethereum Node URLs) that contain IP addresses and public keys for peer discovery and connection.
- **Running the Member Nodes:**
- Each participant runs a Geth node that connects to the private network and participates in block validation and transaction processing.
- **Running a Signer (in Clique):**
- In the **Clique consensus**, designated **signers** validate and sign blocks. These accounts are pre-configured in the genesis file to ensure trusted block production.

Note: Download the genesis file and edit the account details, including the public keys of all participating peers in the network.

Step 1: Installing Geth on Ubuntu

sudo apt update

geth is already the newest version (1.13.14+build29502+jammy).
geth set to manually installed.
0 upgraded, 0 newly installed, 0 to remove and 231 not upgraded.
```

Step 2: Check the version of Geth on the Terminal

geth version

```
ubuntu@ubuntu:~/Desktop$ geth version
Geth
Version: 1.13.14-stable
Git Commit: 2bd6bd01d2e8561dd7fc21b631f4a34ac16627a1
Architecture: amd64
Go Version: go1.21.6
Operating System: linux
GOPATH=
GOROOT=
ubuntu@ubuntu:~/Desktop$
```

3. Step - 3: Create a Private Ethereum Network

1. Create a folder named, private_ethereum_setup

```
ubuntu@ubuntu:~/Desktop$ mkdir private_ethereum_setup
```

2. Create 2 subfolders named node1 and node2 in the folder private_ethereum_setup

```
ubuntu@ubuntu:~/Desktop$ cd private_ethereum_setup/
ubuntu@ubuntu:~/Desktop/private_ethereum_setup$ mkdir node1 node2
```

3. Create 2 accounts in the folder corresponding to node1 and node2

```
ubuntu@ubuntu:~/Desktop/private_ethereum_setup$ geth --datadir node1 account new
INFO [03-31|10:20:39.436] Maximum peer count               ETH=50 total=50
INFO [03-31|10:20:39.438] Smartcard socket not found, disabling  err="stat /run/pcscd/pcscd.
comm: no such file or directory"
Your new account is locked with a password. Please give a password. Do not forget this password.
Password:
Repeat password:

Your new key was generated

Public address of the key:  0x9F9497c56b54890fD2F693BaC26C71e4736eb2bE
Path of the secret key file: node1/keystore/UTC--2024-03-31T04-50-51.743374765Z--9f9497c56b548
90fd2f693bac26c71e4736eb2be

- You can share your public address with anyone. Others need it to interact with you.
- You must NEVER share the secret key with anyone! The key controls access to your funds!
- You must BACKUP your key file! Without the key, it's impossible to access account funds!
- You must REMEMBER your password! Without the password, it's impossible to decrypt the key!

ubuntu@ubuntu:~/Desktop/private_ethereum_setup$ S
```

```

ubuntu@ubuntu:~/Desktop/private_ethereum_setup$ geth --datadir node2 account new
INFO [03-31|10:21:31.739] Maximum peer count          ETH=50 total=50
INFO [03-31|10:21:31.741] Smartcard socket not found, disabling  err="stat /run/pcscd/pcscd.
comm: no such file or directory"

ubuntu@ubuntu:~/Desktop/private_ethereum_setup$
```

6. For configuring the boot node

```
ubuntu@ubuntu:~/Desktop/private_ethereum_setup$ sudo apt-get install bootnode
[sudo] password for ubuntu:
Sorry, try again.
[sudo] password for ubuntu:
Reading package lists... Done
Building dependency tree... Done
Reading state information... Done
bootnode is already the newest version (1.13.14+build29502+jammy).
bootnode set to manually installed.
0 upgraded, 0 newly installed, 0 to remove and 231 not upgraded.
ubuntu@ubuntu:~/Desktop/private_ethereum_setup$
```

```
ubuntu@ubuntu:~/Desktop/private_ethereum_setup$ bootnode -genkey boot.key
ubuntu@ubuntu:~/Desktop/private_ethereum_setup$ bootnode -nodekey boot.key
enode://fbbb379450b32a560c1adbc01f89cd7bf7434c64d3d61140e35f01e4dc6872e079e610606a8127a161a0ed9d7be778636b22552290f7aaabad2e8232ed823eee@127.0.0.1:0?discport=30301
Note: you're using cmd/bootnode, a developer tool.
We recommend using a regular node as bootstrap node for production deployments.
INFO [03-31|10:35:18.634] New local node record          seq=1,711,861,518,633 id=ba197519c6e384da ip=<nil> udp=0 tcp=0
```

4. Step - 4: Establish a Peer-Peer Connection between the nodes along with the bootnode

1. On the first Terminal, Use boot.key to run the boot node

```
ubuntu@ubuntu:~/Desktop/private_ethereum_setup$ bootnode -verbosity 5 -nodekey boot.key -addr 127.0.0.1:30305
enode://fbbb379450b32a560c1adbc01f89cd7bf7434c64d3d61140e35f01e4dc6872e079e610606a8127a161a0ed9d7be778636b22552290f7aaabad2e8232ed823eee@127.0.0.1:0?discport=30305
Note: you're using cmd/bootnode, a developer tool.
We recommend using a regular node as bootstrap node for production deployments.
INFO [03-31|10:40:06.489] New local node record          seq=1,711,861,806,489 id=ba197519c6e384da ip=<nil> udp=0 tcp=0
```

2. On the second Terminal, Run Node 1

```
ubuntu@ubuntu:~/Desktop/private_ethereum_setup$ geth --datadir node1 --port 30306 --bootnodes enode://f7aba85ba369
923bffd3438b4c8fde6b1f02b1c23ea0aac825ed7eac38e6230e5cadcf868e73b0e28710f4c9f685ca71a86a4911461637ae9ab2bd852939b7

```

5. Step - 5 : Exploring the network by attaching JavaScript console to Node 1

1. Fetch network status

```
> net
{
  listening: true,
  peerCount: 1,
  version: "1234",
  getListening: function(callback),
  getPeerCount: function(callback),
  getVersion: function(callback)
}
```

2. To fetch the number of blocks mined

```
> web3.eth.blockNumber
0
> INFO [03-23|12:15:29.133] Looking for peers peercount=1
  tried=0 static=0
```

3. To check the balance of the accounts

```
centage=72 elapsed=0M42.7085
> eth.getBalance(eth.accounts[0])
1.000322e+24
> INFO [03-31|12:09:54.727] Generating DAG in progress
```

4. To fetch the details of the latest mined block

[illegible]

5. To fetch the details of a specific block

[illegible]

6. To check the account balance of the peer machine, provide their Public Key

```
INFO [03-31|12:13:17.464] Looking for peers
> eth.getBalance("0x9f9497c56b54890fD2F693BaC26C71e4736eb2bE")
1.000322e+24
INFO [03-31|12:13:17.464] Looking for peers
```

7. Fetch the details of the peers in the network

```
> admin.peers
[
  {
    caps: ["eth/66", "eth/67", "eth/68", "snap/1"],
    enode: "enode://dce739f3f2fae54667568d84488b8d055409c862e80d78d653bf086b250ddd431fa6c6342502f9ff8f99129b5ee055679fab9335a9049ec7ae1b13941bb265e@127.0.0.1:30307",
    id: "ebf13aa79411d6e216f71bee7625c7391e7a2049d3853aed09ffb5566981dc27",
    name: "Geth/v1.11.6-stable-ea9e62ca/linux-amd64/go1.20.3",
    network: {
      inbound: false,
      localAddress: "127.0.0.1:36900",
      remoteAddress: "127.0.0.1:30307",
      static: false,
      trusted: false
    },
    protocols: {
      eth: {
        version: 68
      },
      snap: {
        version: 1
      }
    }
  }
]
```

8. Perform Transactions between peers in the network

```
> eth.sendTransaction({from:"0x9F9497c56b54890fD2F693BaC26C71e4736eb2bE",to:"0xfc09dce1AB0Fe679e5cC09D88B3E99de13864433"})
WARN [03-31|12:16:19.599] Caller gas above allowance, capping      requested=114,569,871 cap=50,000,000

        input: "0x",
        nonce: "0x1",
        r: "0xa1abb8a85a39d5da37ac14f8275a2eb5034e8182bd4cfa7b3523d631020188f3",
        s: "0xfb96f3fb07299f86289f4a30805b0872a36b091f9c9c65e577de70adb609e11",
        to: "0xfc09dce1ab0fe679e5cc09d88b3e99de13864433",
        transactionIndex: null,

```

12. To check the status of the Mempool - Transaction Pool

```
> txpool.status
{
  pending: 5,
  queued: 0
}
> INFO [03-31|12:21:38.389] Looking for peers                peercount=1 tried=0 static=0
```

Conclusion:-

The experiment successfully implemented a **Private Ethereum Blockchain** using **Geth** and **Clique (PoA)** consensus. By initializing a custom **genesis block**, an isolated network was established for zero-cost testing. This setup proved that authorized signers can effectively validate transactions without the computational overhead of public networks, providing a secure environment for enterprise DApp development.

ITC801 : Blockchain & DLT Lab

Experiment 10

Aim: Explore the Cryptocurrency Landscape

Roll No.	38
Name	Aryan Patankar
Class	D20A
Subject	ITC801: Blockchain and DLT Lab
CO Mapped	CO1:Describe the basic concept of Blockchain and Distributed Ledger Technology. CO2:Interpret the knowledge of the Bitcoin network, nodes, keys, wallets and transactions CO5:Interpret different Crypto assets and Crypto currencies CO6:Analyze the use of Blockchain with AI, IoT and Cyber Security using case studies.

EXPERIMENT NO.10

Name:Aryan Anil Patankar

Class:D20A

Roll No:38

Batch:B

Aim: Explore the Cryptocurrency Landscape

Theory:

This experiment explores the cryptocurrency landscape by combining real-world market data analysis with blockchain technology research. The focus asset for this analysis is **Chainlink (LINK)**, and data was collected from three reputable sources as per the lab requirement:

20.**Financial Data (APIs)** – Services like **CoinGecko** and **CoinMarketCap** provided structured data on market capitalization, circulating supply, and historical 24-hour trading volumes, which are essential for calculating liquidity and asset dominance.

21.**News & Social Platforms** – Platforms such as **CryptoPanic** (news aggregator) and **LunarCrush** (social sentiment) were used to track how public perception and breaking news correlate with price volatility.

22.**Regulatory & Institutional Portals** – Websites like **The Block Pro** or official government portals (e.g., SEC, EU MiCA updates) provided data on legal frameworks and institutional entry.

Cryptocurrency Landscape

- **Definition** – Cryptocurrencies are decentralized digital assets built on blockchain networks, enabling secure, transparent, and immutable transactions without central authority.
- **Market Diversity** – Thousands of cryptocurrencies exist, each serving unique roles:

- **Store of Value (SoV)** – Bitcoin (BTC), characterized by digital scarcity.
- **Utility Tokens** – Chainlink (LINK), Ether (ETH), used to pay for network services.
- **Stablecoins** – USDT, USDC, pegged to fiat (USD) to provide price stability.
- **Governance Tokens** – UNI, AAVE, granting holders voting rights over protocols.
- **Volatility** – Prices are highly sensitive to market sentiment, technological developments, and "macro" regulatory drivers.
- **Data Analysis Importance** – Integrating financial, social, and regulatory data is essential for a holistic understanding of asset performance and market health.

Data Collection Process

The program used the CoinGecko API to automate historical data fetching for Chainlink. The retrieved data was processed with Pandas to compute:

- **Daily Returns** – Percentage change between consecutive days to measure volatility.
- **Moving Averages (MA7, MA30)** – Short-term and long-term trend indicators.
- **Cumulative Returns** – Growth factor over time.
- **Rolling Volatility** – Short-term risk measurement based on daily return fluctuations.

Visualization & Dashboard

Using Matplotlib, a six-panel dashboard was created to display:

17. **Price Trend** – Daily price movement over the selected period.
18. **Price vs Volume** – Correlation between trading activity and price changes.
19. **Daily Returns Distribution** – Statistical spread of daily gains/losses.
20. **Moving Averages** – Technical analysis trend lines for price movement.
21. **Cumulative Returns** – Overall growth performance.
22. **Rolling Volatility** – Market risk trends over time.

Technological Analysis

Beyond market data, the study covered advancements in blockchain technology, including:

- **Consensus Mechanisms** – The shift toward Proof of Stake (PoS) for sustainability and Proof of History (PoH) for faster processing.
- **Scalability Solutions** – Implementation of Layer-2 Rollups (Optimistic and ZK-Rollups) and Sharding to solve the "Blockchain Trilemma."
- **Interoperability Protocols** – Tools like Chainlink CCIP and Polkadot's Relay Chain enabling seamless cross-chain data and value exchange.
- **Privacy Features** – Zero-Knowledge Proofs (ZKP) allowing verifiable transactions without revealing sensitive underlying data.
- **Technical Roadmaps** – Ethereum's focus on "The Surge" (100k+ TPS) and Solana's "Firedancer" client for institutional-grade reliability.

Market Trends & Adoption

13. **Merchant Acceptance** – Significant surge in interest with major processors like Stripe and Shopify integrating stablecoins for global settlement.
14. **Wallet Growth** – Increasing downloads of non-custodial wallets (MetaMask, Phantom), indicating a shift toward direct on-chain interaction.
15. **Network Activity** – Analysis of transaction volumes vs. active addresses to distinguish between "whale" activity and organic retail growth.
16. **Integration with Traditional Finance** – The rise of Real-World Asset (RWA) Tokenization, bringing traditional assets like bonds and real estate on-chain.
17. **Regulatory Developments** – The implementation of frameworks like the EU's MiCA and U.S. FIT21 Act, providing a clear licensing roadmap for the industry

Utilizing Api for analysis and visualization :

Code:

```
import requests
import matplotlib.pyplot as plt
```

```

import pandas as pd
import datetime

# ----- CONFIGURATION -----
# Replace 'YOUR_API_KEY' with the key you got from CryptoCompare
API_KEY = 'YOUR_API_KEY'
SYMBOL = 'LINK'
COMPARISON_SYMBOL = 'USD'
LIMIT = 180 # Number of days

# ----- Fetch Data Function -----
def fetch_cryptocompare_data(symbol, comparison_symbol, limit, api_key):
    url = f"https://min-api.cryptocompare.com/data/v2/histoday"
    params = {
        "fsym": symbol,
        "tsym": comparison_symbol,
        "limit": limit,
        "api_key": api_key
    }

    response = requests.get(url, params=params)
    data = response.json()

    if data['Response'] == 'Success':
        # CryptoCompare returns OHLCV data in 'Data' -> 'Data'
        return data['Data']['Data']
    else:
        print(f"Error fetching data: {data.get('Message')}")
        return None

# ----- Dashboard Function -----
def cryptocompare_dashboard(symbol, comparison_symbol, limit, api_key):
    raw_data = fetch_cryptocompare_data(symbol, comparison_symbol, limit,
api_key)
    if not raw_data: return

    # Create DataFrame
    df = pd.DataFrame(raw_data)

    # Convert 'time' (unix timestamp) to datetime

```

```

df['timestamp'] = pd.to_datetime(df['time'], unit='s')
df.set_index('timestamp', inplace=True)

# Standardize column names to match your previous logic
# 'close' is used as the daily price
df['price'] = df['close']
df['volume'] = df['volumeto'] # Total volume in USD (volumeto)

# Calculate metrics
df['returns'] = df['price'].pct_change()
df['MA7'] = df['price'].rolling(window=7).mean()
df['MA30'] = df['price'].rolling(window=30).mean()
df['cumulative'] = (1 + df['returns']).cumprod()
df['volatility'] = df['returns'].rolling(window=7).std() * 100

# ----- Plotting -----
fig, axes = plt.subplots(3, 2, figsize=(16, 12))
fig.suptitle(f'CryptoCompare: {symbol} Analysis Dashboard',

```

Output:-

Coingecko Website

CoinMarketCap website

Conclusion:-

By combining automated market data processing, visual trend analysis, blockchain technology evaluation, and adoption metrics, this experiment presents a holistic view of the cryptocurrency ecosystem. It demonstrates how blockchain's technical foundations connect with real-world market behavior, providing insights into both current trends and future advancements in the digital asset industry.

ITC801 : Blockchain & DLT Lab

Experiment 11

Aim: Implementation of Hyperledger Fabric Network and Asset Management using Chaincode

Roll No.	38
Name	Aryan Patankar
Class	D20A
Subject	ITC801: Blockchain and DLT Lab
CO Mapped	CO4:Develop applications in permissioned Hyperledger Fabric network.

EXPERIMENT NO.11

Name:Aryan Patankar

Class:D20A

Roll No:38

Batch:B

Aim:To implement a Hyperledger Fabric network, deploy chaincode, and perform asset creation, querying, and transfer operations.

Prerequisites:

- Windows Subsystem for Linux (WSL)
- Ubuntu
- Docker
- Git
- Node.js & npm

Procedure:

Step 1: Update and Install dependencies

Command:

```
sudo apt update  
sudo apt upgrade  
-y
```

```
Aryan@Aryan:~$ sudo apt update
sudo apt upgrade -y
sudo apt install jq curl git nodejs npm -y
[sudo] password for vaishnal:
Hit:1 http://archive.ubuntu.com/ubuntu noble InRelease
Get:2 http://security.ubuntu.com/ubuntu noble-security InRelease [126 kB]
Get:3 http://archive.ubuntu.com/ubuntu noble-updates InRelease [126 kB]
Get:4 http://archive.ubuntu.com/ubuntu noble-backports InRelease [126 kB]
Get:5 http://security.ubuntu.com/ubuntu noble-security/main amd64 Packages [1579 kB]
Get:6 http://archive.ubuntu.com/ubuntu noble/universe amd64 Packages [15.0 MB]
Get:7 http://security.ubuntu.com/ubuntu noble-security/main Translation-en [253 kB]
Get:8 http://security.ubuntu.com/ubuntu noble-security/main amd64 Components [21.5 kB]
Get:9 http://security.ubuntu.com/ubuntu noble-security/main amd64 c-n-f Metadata [10.7 kB]
Get:10 http://security.ubuntu.com/ubuntu noble-security/universe amd64 Packages [1170 kB]
```

Step 2: Clone Fabric

Sample Command:

git clone

<https://github.com/hyperledger/fabric-samples> cd

fabric-samples

```
Aryan@Aryan:~$ git clone https://github.com/hyperledger/fabric-samples
cd fabric-samples
Cloning into 'fabric-samples'...
remote: Enumerating objects: 15618, done.
remote: Counting objects: 100% (238/238), done.
remote: Compressing objects: 100% (129/129), done.
remote: Total 15618 (delta 161), reused 109 (delta 109), pack-reused 153380 (from 3)
Receiving objects: 100% (15618/15618), 24.07 MiB | 390.00 KiB/s, done.
Resolving deltas: 100% (8809/8809), done.
```

Step 3: Install Fabric Command:

curl -sSLO

<https://raw.githubusercontent.com/hyperledger/fabric/main/scripts/install-fabric.sh>

chmod +x

install-fabric.sh

./install-fabric.sh docker samples binary

```
Aryan@Aryan:~/fabric-samples$ curl --SSL0 https://raw.githubusercontent.com/hyperledger/fabric/main/scripts/install-fabric.sh
chmod +x install-fabric.sh
./install-fabric.sh docker samples binary

Clone hyperledger/fabric-samples repo

==> Already in fabric-samples repo
fabric-samples v2.5.15 does not exist, defaulting to main. fabric-samples main branch is intended to work with recent versions of fabric.

Pull Hyperledger Fabric binaries

==> Downloading version 2.5.15 platform specific fabric binaries
==> Downloading: https://github.com/hyperledger/fabric/releases/download/v2.5.15/hyperledger-fabric-linux-amd64-2.5.15.tar.gz
==> Will unpack to: /home/Aryan/fabric-samples
```

% Total	% Received	% Xferd	Average Speed	Time	Time	Time	Current
			Dload Upload	Total	Spent	Left	Speed
0	0	0	0	0	0	0	0
100	120M	100	120M	0	0	0	487k

Step 4: Verify Installation Command:

docker images | grep fabric

```
Aryan@Aryan:~/fabric-samples$ docker images | grep fabric

```

Step 5: Set Environment

Variables Command:

```
export PATH=$PATH:$HOME/fabric-samples/bin
```

```
export FABRIC_CFG_PATH=$HOME/fabric-samples/config
```

```
peer version
```

```
Aryan@Aryan:~/fabric-samples$ export PATH=$PATH$HOME/fabric-samples/bin
export FABRIC_CFG_PATH=$HOME/fabric-samples/config
Aryan@Aryan:~/fabric-samples$ peer version
peer:
Version: v2.5.15
Commit SHA: 83c7930
Go version: go1.20.0
OS/Arch: linux/amd64
Chaincode:
Base Docker Label: org.hyperledger.fabric
Docker Namespace: hyperledger
```

Step 6: Start Network Command:

cd ~/fabric-samples/test-network

./network.sh up createChannel

```
aryan@Aryan:~/fabric-samples$ cd ~/fabric-samples/test-network
./network.sh up createChannel
Creating channel 'mychannel'.
If network is not up, starting nodes with CLI timeout of '5' tries and CLI delay of '3' seconds and using
ldp with crypto from 'cryptogen'
LOCAL VERSION=v2.5.15
DOCKER IMAGE VERSION=v2.5.15
/home/aryan/fabric-samples/test-network/./bin/cryptogen
Generating certificates using cryptogen tool
Creating Org1 Identities
+ cryptogen generate --config=./organizations/cryptogen/crypto-config-org1.yaml --output=organizations
Creating Org2 Identities
+ cryptogen generate --config=./organizations/cryptogen/crypto-config-org2.yaml --output=organizations
Creating Orderer Org Identities
+ cryptogen generate --config=./organizations/cryptogen/crypto-config-orderer.yaml --output=organizations
Generating CLP files for Org1 and Org2
[+] up 7/7
✓Network fabric_test Created
✓Volume compose_peer0.org1.example.com Created
```

Step 7: Deploy Chaincode Command:

./network.sh deployCC \

-ccn basic \

-ccp ../asset-transfer-basic/chaincode-javascript \

-ccl javascript

```
++ configtxlator proto_encode --input /home/vaishnal/fabric-samples/test-network/channel-artifacts/config_update_in_en
velope.json --type common.Envelope --output /home/vaishnal/fabric-samples/test-network/channel-artifacts/Org2MSPanchors.
2026-04-09 17:04:04.975 UTC 0001 INFO [channelCmd] InitCmdFactory -> Endorser and orderer connections initialized

+ peer lifecycle chaincode package basic.tar.gz --path ../asset-transfer-basic/chaincode-javascript --lang javascript --label basic_1.0

```

Step 8: Set Peer

Environment Command:

```
export CORE_PEER_TLS_ENABLED=true
```

```
export
```

```
CORE_PEER_LOCALMSPID="Org1MSP"
```

```
export
```

```
CORE_PEER_TLS_ROOTCERT_FILE=$HOME/fabric-samples/test-network/organizations/peerOrganizations/org1.example.com/peers/peer0.org1.example.com/tls/ca.crt
```

```
export
```

```
CORE_PEER_MSPCONFIGPATH=$HOME/fabric-samples/test-network/organizations/peerOrganizations/org1.example.com/users/Admin@org1.example.com
```

e.com/msp

export CORE_PEER_ADDRESS=localhost:7051

```
aryan@Aryan:~/fabric-samples/test-network$ export CORE_
PEER_TLS_ENABLED=true
export CORE_PEER_LOCALMSPID="Org1MSP"
export CORE_PEER_TLS_ROOTCERT_FILE=$HOME/fabric-samples/te
est-network/organizations/peer/org1.example.com/tls/ca.crt
export org1.example.com/peers/peer0.org1.example.com/tls/ca.crt
export CORE_PEER_MSPCONFIGPATH=$HOME/fabric-samples/set
test-network/organizations/peer/org1.example.com/peer0
organizations/org10.com/peer
peer0organizations/org1.example.com/users/Admin@org1.example.com/
```

Step 9: Initialize Ledger Command:

```
peer chaincode invoke \
-o localhost:7050 \
--ordererTLSHostnameOverride orderer.example.com \
--tls \
--cafile
"$HOME/fabric-samples/test-network/organizations/ordererOrganizations/example.com/orderers
/orderer.example.com/msp/tlscacerts/tlsca.example.com-cert.pem" \
-C mychannel \
-n basic \
--peerAddresses localhost:7051 \
--tlsRootCertFiles "$CORE_PEER_TLS_ROOTCERT_FILE" \

```

```
Aryan@Aryan:~/fabric-samples/test-network$ peer chaincode invoke \
-o localhost:7050 \
--ordererTLSHostnameOverride orderer.example.com \
--tls \
--cafile "$HOME/fabric-samples/test-network/organizations/ordererOrganizations/example.com/orderers/orderer.example.com/msp/tlscacerts/tlsca.example.com-cert.pem" \
-C mychannel \
-n basic \
--peerAddresses localhost:7051 \
--tlsRootCertFiles "$CORE_PEER_TLS_ROOTCERT_FILE" \
-c '{"function": "InitLedger", "Args": []}'
2026-04-09 17:26:44.205 UTC 0001 INFO [chaincodeCmd] chaincodeInvokeOrQuery -> Chaincode invoke successful. result: status:200
Aryan@Aryan:~/fabric-samples/test-network$
```

Step 10: Query Assets Command:

```
peer chaincode query -C mychannel -n basic -c '{"Args":["GetAllAssets"]}'
```

```
-n basic \
-c '{"Args":["GetAllAssets"]}'
[{"AppraisedValue":300,"Color":"blue","ID":"asset1","Owner":"Tonoko","Size":5,"docType":"asset"}, {"AppraisedValue":400,"Color":"red","ID":"asset2","Owner":"Brad","Size":5,"docType":"asset"}, {"AppraisedValue":500,"Color":"green","ID":"asset3","Owner":"Jin Soo","Size":10,"docType":"asset"}, {"AppraisedValue":600,"Color":"yellow","ID":"asset4","Owner":"Max","Size":10,"docType":"asset"}, {"AppraisedValue":700,"Color":"black","ID":"asset5","Owner":"Adriana","Size":15,"docType":"asset"}, {"AppraisedValue":800,"Color":"white","ID":"asset6","Owner":"Michel","Size":15,"docType":"asset"}]
```

Step 11: Create Asset Command:

```
peer chaincode invoke \
-o localhost:7050 \
--ordererTLSHostnameOverride orderer.example.com \
--tls \
--cafile
"$HOME/fabric-samples/test-network/organizations/ordererOrganizations
/ex
ample.com/orderers/orderer.example.com/msp/tlscacerts/tlsca.example.co
m-c ert.pem" \
-C mychannel \
-n basic \
--peerAddresses localhost:7051 \
--tlsRootCertFiles "$CORE_PEER_TLS_ROOTCERT_FILE" \
-c '{"function":"CreateAsset","Args":["asset9","blue","10","Manav","500"]}'
```

```
arvan@Arvan:~/fabric-samples/test-network$ peer chaincode invoke \
-o localhost:7050 \
--ordererTLSHostnameOverride orderer.example.com \
--tls \
--cafile "$HOME/fabric-samples/test-network/organizations/ordererOrganizations/example.com/orderer.example.com/msp/tlscacerts/tlsca.example.com/cacerts/tlsca.example.com-cert.pem" \
-C mychannel \

Removing generated chaincode docker images
```

Result:

The Hyperledger Fabric network was successfully implemented.

Chaincode was deployed and asset operations such as creation, querying, and transfer were performed successfully. The asset was created with owner name **Manav**, confirming correct execution.

Conclusion:

This experiment demonstrated how blockchain networks work using Hyperledger Fabric and how transactions are securely executed. The experiment also helped in understanding real-time asset management using smart contracts.

Roll No.	38
Name	Aryan Patankar
Class	D20A
Subject	ITC801: Blockchain and DLT Lab Questions ● Draw a neat diagram and explain components of Hyperledger Fabric? ● Draw a neat diagram and explain the transaction flow in Hyperledger Fabric? ● State the requirements of a consensus algorithm. Explain PAXOS and kafka consensus ● Explain ERC 20 token standard and its functions and Compare how ERC 20 token is different than ERC 721 token ● What is Tokenization? Explain its significance and challenges/limitation with example ● Compare Fungible and non Fungible tokens (Give examples of each) ● How can blockchain-based IoT networks improve device management, data monetization, and user privacy in the rapidly growing IoT ecosystem? ● In what ways can blockchain technology enhance transparency, security, and efficiency in government services and record-keeping? Discuss the challenges and benefits of implementing blockchain-based voting systems for elections.

Aim: Assignment 3

Roll No.	38
Name	Aryan Patankar
Class	D20A
Subject	ITC801: Blockchain and DLT Lab Q1 Analyze & compare different consensus mechanisms such as PoW, PoS, Delegated Proof of Stake & PBFT in terms of security, scalability, energy efficiency & fault tolerance. Illustrate your answer with examples like Bitcoin & Ethereum. Q2 Analyze different types of nodes in a blockchain network & explain their role in maintaining the system. Compare how each node contributes to validation, storage & network efficiency. (Compare UTXO model) Q3 Analyze the UTXO model & explain how it ensures transaction transparency & security in blockchain systems. Illustrate with an example such as Bitcoin. Q4 Explain crypto asset & cryptocurrency. Examine & analyze the role of different types of crypto assets (utility tokens, security tokens, crypto coins) in the blockchain ecosystem. Evaluate their impact on digital finance & decentralized applications. Q5 Analyze the role of payment scripts in blockchain transactions. Examine & analyze different types of payment scripts. Explain how they ensure secure & verifiable transfer of coins. Illustrate with an example. Q6 What is a smart contract? Explain lifecycle of smart contracts. Explain advantages, limitations, risks & opportunities of smart contracts. Q7 Explain the structure of BTC transaction & ETH transaction. Q8 Explain the difference between mining & minting and explain the process
